[1793]

Foreign Philosophical Chemists.

IN a country fuch as Britain, distinguished for its liberality, sense, and generosity, and where a Society is established by Royal munificence, for the encouragement of science. it appears fingular that a Briton should have to feek patronage and protection from foreigners: but fuch is the case. - I have called upon my countrymen, both collectively and individually, to give my doctrines a candid and fair discussion; but they have not hitherto had the liberality to do it. They, from their labours, have received great honours for supposed discoveries. But Philosophy knows no partialities,—she only venerates truth; and that man deferves not the name of a philosopher, who would skulk from investigation. It is investigation that I want: therefore I hope I shall receive it from you. In the great field of science, each labourer is a citizen of the world, and his appeal is to it. If, upon a fair and public examination, my fystem is found fallacious, I shall willingly give it up; for truth is my object.

My fystem is a more extensive one than has hitherto been given to the world; for it

A 2

not

not only comprehends fire through all its fituations in nature, but the important formation and purpofes of air, and particularly its uses in animal and vegetable life, besides many other chemical phenomena; embracing all the experiments and phenomena of modern chemistry, and appealing to the late numerous experiments for its evidence.—Therefore I hope from you it will have a candid examination; and that honour will be your reward, at least that pleasure which proceeds from a liberal action.

I am, Gentlemen,

With the greatest Respect, Your most obedient humble Servant,

CARLISLE, July 10, 1793. ROBERT HARRINGTON.

These Essays would have been published in the spring, had I not been waiting for the next volume of *The Philosophical Transactions*, in order that I might have made my observations upon any chemical papers it contained; as I suppose our chemical philosophers still continue to work in their unproductive mine:—but it is so long in being published, that I have not feen it.

Both Dr. Crawford and Mr. Keir have promifed the Society an explanation of fome experiments and phenomena, upon their principles, which they have not done. To what must we impute it? I should suppose they find themselves aground.

CHEMICAL ESSAYS.

A CONTINUATION OF REFLECTIONS UPON FIXED FIRE, THE FORMER PART BEING PUBLISHED IN THE GENTLEMAN'S MAGAZINE FOR 1792.

I SHALL now consider the effervescence of nitrous and pure airs. The phenomenon of nitrous air being united to pure air has greatly astonished modern chemists. They decompound each other. When this is investigated, it will, I believe, be found to proceed from the common principle of an acid body uniting to an alkaline one.

The only airs we are acquainted with that will unite and decompound each other, are alkaline and acid airs; viz. the vitriolic acid air, the aerial acid air, and the marine acid air; these unite with alkaline air, forming the vitriolic, the common, and the marine ammoniac. The nitrous air, which, agreeable to my doctrine, I suppose the nitrous acid united to phlogiston, will not unite with alkaline air. The reason appears to be this; the nitrous acid has so strong an attraction for its phlogiston and aerial state, that it cannot be decompounded. But if these two airs are united,

B

nitrous

and the electrical spark be taken in them, the electrical fire will assist the alkaline air to decompound the nitrous air; and, by a very few slight strokes, they will decompound each other, forming the nitrous ammoniac.

But expose nitrous air to pure air, and they will produce the same effect, i. e. decompound each other; and we shall find, upon investigation, that they do it upon the same principle as the acid and alkaline airs, uniting together. And this I should suppose a leading argument to prove that pure air is formed of similar constituent parts to alkaline air, as it shews a similar effervescence when decompounded, and turns the nitrous air red, producing heat in the decomposition.

There is no occasion here to resume the arguments tending to prove, that the fire which forms fixed air and water into pure air, is something of a similar concentration to the fire that composes alkalies; especially as I have elsewhere proved, that the pure air formed from nitre consists of the acid, alkali, and water aeralized together: and that the acid being phlogisticated by being aeralized with the alkali, weakens its attraction for the alkali. This is seen in nitre, which, when long exposed to heat, its acid will become so phlogisticated, that the vegetable acid, (as Mr. Scheele found) will expel it from the alkali. Therefore the nitrous acid in the nitrous air will

artack the alkali, and produce such a fermentation as to decompound both airs. That this is owing to the acid in the nitrous air, is evident; for if it is neutralized so as not to affect the vegetable juices, it will not decompound pure air, as in nitrous dephlogisticated air. And still more particularly, if the pure nitrous vapour is united to alkaline air, or pure air, it will (as Dr. Priestley found) decompound them as quick as nitrous air.—See vol. III. p. 193.

But to know whether this theory, or that of Mr. Lavoisier, is the true one, the best test would be accurately to examine the residuum. If, according to Mr. Lavoisier, the nitrous acid is formed of pure air and nitrous air, we should be able to form the pure nitrous acid. But, agreeably to my theory, the nitrous air is formed of the nitrous acid and plogiston, and pure air of an acid and water united, with a concentration of fire simito an alkaline saturation; or, as when the latter is made from nitre with the real alkali, only volatilized, and by that means united with more loose fire, and therefore much more easily set loose as aerial fire.

Moreover, by accurately examining the refiduum, which has not as yet been properly attended to, we shall know what hypothesis we ought to adopt. The two airs having a strong attraction for each other, produce the same phenomena; as for inftance, if an acid air, the vitriolic acid air, and the alkaline air were united together: therefore uniting them in that proportion, fo as to faturate each other, they should form the pure nitrous acid. But they form a highly phlogisticated nitrous acid, so highly, that if the decomposition is made over water; the acid receiving water, (which I have fully proved to be the body that composes airs) will again produce nitrous air in the greatest abundance, and the residuum itself will be highly plogisticated.

Dr. Prieftley fays,—" The faturation of water with nitrous acid from nitrous air, by means of deplogifficated air, makes a pleafing experiment, on account of the great quantity of nitrous air decomposed by this means at one process, the quickness with which the decomposition is made, and the visible effect of the sudden impregnation on the water. For the surface of it instantly becomes, as it were, oily, descending in waves from the top to the bottom of the water, while nitrous air issues from the bottom and sides of the vessel; a most remarkable phenomenon, of which a full account will be given in a proper place."

Now, will Mr. Lavoisier grant, that upon the nitrous acid formed from the decomposition of nitrous air, pure air is imbibed by the water,

the water chemically attracting it, so as again to form nitrous air? If not fo, how came it to be formed again? But we are still aground, for the rest of the acid is highly phlogisticated. To this chemical philosophers may answer, that the phlogiston is owing to its not being fully saturated with pure air. But if there is a greater proportion of dephlogisticated air than the nitrous acid can decompound, the phenomenon is the fame .--Then what hinders the full faturation? Are we acquainted with any bodies which have a strong affinity for each other, that will rush together with fo strong an attraction, but will perfectly faturate each other? Will alkalies or earths not faturate acids? Or take any chemical bodies you pleafe. Why then can we make the pure nitrous acid; or how will the acid, when it has gotten its watery base again form fresh nitrous air?

In my Thoughts on Air, published in 1785, I have, I think, satisfactorily proved, that nitrous air is formed of the nitrous acid, phlogiston, and water aerilized by heat. Therefore, in the decomposition or fermentation between the pure air and the nitrous air, the heat which formed the union between the water, and the phlogisticated acid is set free, in consequence of which the water is precipitated. But when it again meets with water and heat from the fermentation, nitrous air is again produced. However as we have already

fhewn in pure air, its fire is so loosely concentrated, that sermentation, combustion, or muscular action can easily set it loose as actual heat; its acid is precipitated in its fixed state in this process of the mixing pure air and nitrous air together, in the same manner as if done by combustion, forming the same acid as that with which it is united; as when phosphorus, or sulphur, is burned with it, they form the phosphoric or sulphurous acids.*

It should not be matter of surprise, that two airs unite together and decompound each other of their

* "This is Mr. Lavoifier's grand argument for supposing, that the oxygen gas, with a great part of its caloric, is condensed into the nitrous acid; or when the nitrous and oxygen gas decompound each other, that they will comparatively produce little heat. But the cause is this, in their condensation, the greatest part of their fixed fire or phlogiston is not set loose or free, but is condensed with the airs.

"For, according to our theory, we have shewn that pure air must necessarily possess both fixed fire and an acid, in order to support combustion. The same argument will take place when the factitious dephlogisticated air, from the calx of metals and the nitrous acid are decompounded by the nitrous air: for the nitrous acid of the nitrous air attracts the fixed fire, which is neutralized or concentrated with the acid, water, and a small part of the earth of the calx, which form oxygen gas, as having a stronger attraction for the fire than the airs acid have. Dephlogisticated nitrous air, which is a compound of the nitrous acid and phlogiston, more amply confirms this doctrine; for the nitrous air will not decompound it; its acid being equally as strong, being the same acid, as that which the nitrous air possesses; i. e. being weakened

their aerial form, fince all acid and alkaline airs do it. We fee that fulphur, iron, and water will effervesce and decompound their phlogiston into actual fire.

But there is another aerial body, viz. the nitrous vapour, which will decompound nitrous air, and which their received chemical theories cannot account for.† "This vapour," fays Dr. Priestley, vol. II. p. 169, "is the pure nitrous " vapour of the acid, which is instantly and wholly " imbibed by the water." Here it appears that the pure nitrous vapour will likewife decompound nitrous air. Hence, according to Mr. Lavoisier's theory, the vapour, or the nitrous air, must either give or receive pure air from each other, which ever he chooses to make it. But then, if it was the vapour that gave the pure air, it either should (after the process) have formed nitrous air or phlogisticated air. But here is a loss instead of a generation of airs; and only one-fourth part of

weakened by no operation, but what the nitrous acid itself has undergone." Bewley's Treatise on Air, p. 101.

† Dr. Priestley says,—" I exposed to this nitrous vapour, common air, instantable air, and fixed air, and all of them for a considerable time, without making the least sensible alteration in any of them. It is possible that a longer continuance of the process might have affected them; but a great deal less time was abundantly sufficient for this acid vapour to produce its utsmost effect upon nitrous air."—Vol. II. p. 171.

the nitrous air remains. Befides, it is making the nitrous air decompound the nitrous acid; or vice versa, the nitrous acid the nitrous air. But according to my theory, the nitrous acid applied in the powerful state of vapour, (for water alone can calcine iron, when aided with heat in the form of vapour) will penetrate into the nitrous air, attacking its phlogiston, and producing an effervescence, so as to decompound the nitrous air.

In attending to the different writers upon phlogiston, either for or against it, the following reflection necessarily occurs; that of the phenomena of the numerous experiments which have been made, some are made use of to contradict the one hypothesis, and some the other. However, it appears from their own writings, that the great body of the phenomena contradict both hypotheses. As Dr. Higgins has treated extensively of this subject in his late publication, I beg leave to make a few observations upon it.

Dr. Higgins fays, p. 200,—" Equal parts of dephlogisticated and light inflammable air, mixed over water, will form, according to Mr. Kirwan, a dense white cloud; more than one half is absorbed, and is found to be common marine acid, and the residuary air is pure insections."

Now, this fact is certainly a very flrong proof that

that there is such a body as phlogiston, and that it forms dephlogisticated marine acid into the common marine acid. Dr. Higgins, to combat this strong experiment, says,—"That there is no "fixed air formed in the process," which, according to Mr. Kirwan's theory, there ought to be. So one error is opposed to another. There certainly is not any fixed air formed, nor ought there to be any formed in the process. Our chemists of great name are so enveloped in, and embarrassed with theories, that they find themselves aground in expounding any phenomenon.

Dr. Bewley, fays, p. 173,-" There is an expe-" riment mentioned by Dr. Higgins, which he " fays in favour of Mr. Lavoisier's system; as " indeed we must agree with him, that it is " directly contradictory to the fystem of phlogis-" ton, with the belief that dephlogisticated air is, " in reality, dephlogisticated. But if Dr. Higgins " and others will please to see the truth, this de-" phlogisticated nitrous air is formed of the ni-" trous acid and the phlogiston of the copper:-"it will be a strong proof in favour of the doc-"trine of phlogiston. The Dr. says, p. 550,-" If tin be introduced into a neutral folution of " the tin in the nitrous acid, it is calcined, a calx " is thrown down, and the dephlogisticated or " imperfect nitrous air is produced. Dephlogif-" ticated nitrous air, according to the phlogistians, " contains

"contains no phlogiston; then I ask, what becomes of the phlogiston of the newly calcined
metal? If tin contained phlogiston, either instream flammable air or nitrous air would be produced,
or a portion of the dissolved tin would be precipitated in its metallic state; neither of which
will take place, if the experiment be well conducted. Hence I should suppose, that metals
do not precipitate each other in their metallic
state, in consequence of a double affinity proceeding from the matter of light inflammable
air, or phlogiston; and likewise that metals
part with no such thing during their calcination
in acids."

Dr. Higgins fays, in his last publication, p. 49, -" I introduced fome iron nails, free from ruft, " into ffrong volatile vitriolic acid; when it flood " for a few minutes, it acquired a milky appear-"ance, and the folution went on without ebulli-"tion or extrication of air. On standing for a "few hours, the folution acquired a darkish " colour, and a black powder was precipitated. "This powder, when collected and washed, put " on red-hot iron, burned partly like fulphur, and " and partly like charcoal dust, and the incom-"bustible residuum was of a purplish colour. "The filtered folution was perfectly neutralized, " and free from the least sulphurous pungency.-Its tafte was strongly chalybeate, but not so " disagreeable " disagreeable as that of the solution of iron in the perfect vitriolic acid, or in any of the mineral acids.

"Nitrous acid dropped into the folution in"flantly produced a cloudiness, which immedi"ately disappeared without cbullition, though
"volatile sulphurous acid was disengaged in its
"utmost degree of pungency. The vitriolic
"marine, and nitrous acids decomposed the solu"tion, but caused no turbidness, nor was any
"inflammable air produced."

Nothing can be more obvious than this experiment. The volatile vitriolic acid being previoully united to a large proportion of phlogiston, confequently united itself to the phlogiston of the iron in a very gentle manner; its activity being taken away by the previous faturation. However it decompounds the iron, attracting a quantity of its phlogiston sufficient to form sulphur. This agrees with my theory; that when the acid and the phlogiston unite so gently as not to produce any great heat, they form no kind of air; neither the vitriolic acid, nor inflammable airs, but fulphur. Of which this is a proof; if you drop into the folution another acid, which has a stronger attraction for the metal's phlogiston, the volatile vitriolic acid will be fet loofe in the same state in which it was applied to the iron.

The present chemical doctrines have given rise

to very fingular theories and constructions of the different phenomena. Dr. Higgins says, p. 163, — "From the process of these experiments, I did "not hesitate to conclude, but that which is called dephlogisticated nitrous air, is common nitrous air deprived only of a portion of its dephlogisticated air." The experiment which gave birth to these opinions is this; by exposing nitrous air to iron, the iron is reduced into a calx, and the nitrous air turned into a dephlogisticated air.*

Let us try in what manner this coroborates my theory. The acid which is not neutralized in nitrous air, (this is feen by its turning the vegetable juices red) will act upon the phlogiston of iron and unite with it, receiving fo strong a saturation as to form this air, in which a candle burns with an enlarged flame. From the experiment which Dr. Higgins made, he is fo strongly confirmed that, dephlogisticated air is imbibed by the calx of iron, as to fay, "These facts leave " no room to doubt, but that dephlogisticated air " contains less dephlogisticated air than the com-" mon nitrous air." What must we say of doctrines which lead those who maintain them to such conclusions? That an air which admits a candle to burn in it with fuch a strong and enlarged flame,

^{*} But this air is very different from the oxygen gas of chemilts, or pure air; for it is as noxious to animal life as the most mephitic air.

should possess less dephlogisticated air, than nitrous air which immediately extinguishes slame, the same as pure phlogisticated air! Such however are the errors which flow from these doctrines.

The above mentioned author fays, (last publication, p. 164)-" Dr. Priestley has discovered a " species of nitrous air which supports combustion, " destroys animal life, and is condensible in water. "This he has called dephlogisticated nitrous air. "I confider dephlogisticated nitrous air to be the " last stage of nitrous acid, and to be less under-" flood than the four preceding. I exposed four " equal quantities of nitrous air in different tubes, " to a nearly equal proportion of iron and water. "In three weeks the air was diminished one fixth, "and the refiduum extinguished a candle, and " reduced common air. In three weeks more it " was reduced about one fourth, and the refiduum " fuffered a candle to burn in it faintly. When it " flood a fortnight longer, the diminution was " nearly one third of its bulk, and a candle burned " in the residuum with an enlarged same. I let the " other tube stand until the air contracted to more "than one third of its original bulk; the refiduum " was phlogisticated air and had the smell of vo-" latile alkali.* From the progress of these expe-" riments

^{*} This also agrees with my theory. I suppose that the volatile alkali is formed of a neutralization of fire, similar to inflammable

" riments I did not hesitate to conclude, but that " which is called dephlogisticated nitrous air, is " common nitrous air, deprived only of a portion " of its dephlogisticated air. Dr. Priestley found " that nitrous air, which stood in contact with iron " and water for four months, extinguished a can-" dle. He likewise found that a candle burned " with an enlarged flame in nitrous air which had " been in contact with iron, over mercury, about " fix months. The fame philosopher found, that " nitrous air, exposed to liver of fulphur for a day, " was diminshed one third of its bulk; a candle " burned in the remainder with an enlarged flame, " and it was not in the least diminished by nitrous "air. I have frequently observed that nitrous "air, when reduced to two thirds of its bulk, " always admitted a candle to burn in it with an "enlarged flame; but that in proportion as it " got below this standard, it supported stame so " much the worfe, until it was reduced nearly to " one third, when it excinguished a candle."

I have quoted this passage, because the phenomena mentioned in it, Dr. Higgins says, are not presumed to be accounted for by their theory. I beg leave to mention my explanations to this learned society. Airs in which bodies burn are

inflammable air; and therefore in the last stage of this process it attracted the inflammable air, or phlogiston of the air, and lest it in a state of azote, which I suppose the least saturation of phlogiston.

combustible

combustible as well as the bodies themselves. They confist of an acid and concentrated fire; and the reason why they are necessary to combustion is, that their fire is more eafily fet loofe than that of the combustible bodies; in consequence of which, the ignition of the airs produces the ignition of the combustible bodies. An author already quoted fays, (Treatife on Air, p. 29.) " A combustible " body, though fire is applied to it will not burn " without the agency of another body. The great " agent in nature is atmospherical air, which is a " compound of an acid and phlogiston. But be-" ing composed of a mild acid, and not possessing " a high concentration of fixed fire, parts with its "fixed fire, when actual fire is applied to it; "however, the heat it produces is not powerful " enough to keep the air burning, or decom-" pounding its own fixed fire, unless it is exposed " to fome combuftible body having a high con-" centration of fire."

The reason why Homberg's pyrophorus will burn in nitrous air, but not in dephlogisticated air, is (as I have proved in my thoughts on air) that all pyrophori consist in being formed of a loosely attracted fire, like lime; consequently acids and acid airs will expel it. And, for this reason, if we drop the nitrous acid upon the pyrophorus, it will turn it into a red hot coal. That dephlogisticated nitrous air will not decompound pure

air, is owing to its acid being perfectly neutralized with phlogiston, and for the same reason it will not turn the vegetable juices red, which nitrous air will do.*

As chemical investigations are at present the favourite pursuit, and as experiments are multiplied, so each chemist being under the influence of some theory, endeavours to find out experiments which may favour it. The fellowing affertions may, perhaps, be thought too bold; yet I will venture to fay, I never heard of one chemical experiment but may be rationally explained upon the principles of my theory, and upon no other.

I am happy to find that Dr. Priestley, after diversifying his experiments upon the burning of inflammable and pure airs, has at last drawn the same conclusions I did some years ago. In my thoughts on air (published in 1785) is the following passage, (p. 328.) "We cannot possibly mistake these experiments; when the inflammable air was in less proportion to the empyreal air, the residuum of water, after the explosion, was acid; but with a greater proportion of inslammable air the residuum of water had not this

" acidity.

^{*} I mention these experiments, as being inexplicable (agreeably to Dr. Higgins) by their theories. And from the nitrous acid setting loose so instantaneously the fire of the pyrophori, shews clearly in what manner it operates upon volatile oils, setting loose their fixed sire.

" acidity. And likewise this acid residuum was " of the nitrous kind. As then the acidity of the "water and phlogistication of the air alternate "with each other, as the one takes place the other " is not to be found: we cannot have a doubt but "it is from this cause. That when there is a small "proportion of inflammable air exploded with " the empyreal air, the fire will be fufficient to " fet loose the quiescent fire or phlogiston of the " empyreal air, so as to turn it again to the nitrous acid from which it was made: but when "there is a greater proportion of inflammable " air, fo as to give fufficient phlogiston to the " acid to unite with it, they forcibly attract each "other, and generate phlogisticated air which " makes the explosion. But this phlogisticated " air is undoubtedly made by the union of the " acid fet free from the decompounded empyreal " air, and united with the phlogiston of the in-" flammable air: for the purest empyreal air is " made use of in the process. And this same em-" pyreal air may, by burning or by bees breathing " in it, be all turned to an acid air; therefore there " cannot be the most distant supposition of this " phlogisticated air being previously formed in the " empyreal or inflammable air; but is in reality " generated at the time of the explosion."

And in my letter to Dr. Priestley and others, (published in 1788,) I thus express myself, (p.

125.) "Or take a quantity of the empyreal air, and burn it with a small proportion of inflam- mable air, and there will be an acid in the re- fiduum; and then take the same quantity of the fame kind of empyreal air, and burn it with a full proportion of inflammable air, and there will be no acid left." Again, (p. 127.) "This theory is most strikingly shewn, in firing in- flammable air and empyreal air. If there is a full proportion of inflammable air, there will be fuch a degree of fire set loose, as to sty off with the acid; (as we have before explained,) but if there is a less proportion of inflammable air, so as not to produce so great a heat, the acid will be set left in the residuum."

According to their theories it was supposed, that in these experiments a surplus of either air would remain unchanged after the operation, without effecting the result. This should really be the case, were these two airs united together upon the same principle as that of two bodies saturating each other. But as it is a process of burning, consuming, or setting free fixed fire, which makes so considerable a part of these airs, so the explanation now given of it by Dr. Priessley, is in direct opposition to their theories. He says there is an acid in the residuum, and phlogisticated air is a compound body, formed of the nitrous acid and phlogiston. How then can phlogisticated air be one of the bodies

bodies which goes to the composition of the nitrous acid? This experiment, if due attention is paid to it, can be explained only on the principles of my theory.

I flatter myself that this very learned society will, without prejudice or prepossession of any kind, candidly consider and weigh my explanations of the different chemical phenomena mentioned in this paper. For I am apt to believe, that the theories which modern chemists have been, from their experiments, led to adopt, will, upon discussion, be found inadequate to account for these phenomena; but that mine gives a consistent and satisfactory explanation of them all.

Chemical philosophers have been imperceptibly lead to adopt their present hypotheses without considering the wild conclusions deducible from them. They have supposed most bodies in nature, to be formed of airs; the waters of the ocean, acids, salts, &c. But it is an incontrovertible sact, that in making any body, the ingredients of which it is composed, must be previously formed before they are united or mixed. Then, I would ask philosophers, what space that we are acquainted with, would be sufficient to hold these ingredients; viz. pure, inflammable, phlogisticated, and nitrous airs? The great expansive space between planet and planet would be insufficient. Here nature would be inadequate to herself.—Again; if water is

formed of pure and inflammable airs; and (conformable to the prefent theories) with fuch an immense quantity of caloric, as we have shewn it must possess, what would follow from this? For instance, in the folution of iron, they fay water is decompounded, one of the bodies forming inflammable air, and the other very pure air which enters the calx. The aurum fulminans is capable of exploding with great violence. All this fire (agreeably to the doctrines of modern chemists) comes from the condenfed pure air in the calx, uniting with the inflammable air of the volatile alkali. Bur were this fame condenfed pure air to explode with the inflammable air in its aerial state, it must produce a far more wonderful explosion, as it would have the amazing quantity of caloric the inflammable air possesses in its aerial state. Dr. Crawford, from his experiments, fays, the caloric it possesfes is 21,4000; whilft dephlogisticated air possesfes only 4,7490. From this it would appear, that water possesses more caloric than the two bodies of which it is formed, in their aerial state. Therefore, in burning these two bodies into water, how can we agree with Mr. Lavoisier, who says they give out caloric in this quantity:

From 1 lib. of hydragon gas 295,58950. From 1 lib. of oxygen gas 52,16280.

They ought, in their formation into water, to have produced fo much cold.

Gentlemen,

Gentlemen, furely theories which lead to conclusions fo very extravagant, should be more maturely considered before chemists adopt them. Were this the case, they would be discovered to be founded in error. The ocean is formed of the two most combustible bodies in nature; but at this rate, presumptuous man, might have it in his power, with such an immense quantity of caloric, as we are told the water possesses, to set it on fire! But the Deity takes such care of his works, that man, though willing, cannot have it in his power to destroy any of them. He may make experiments, adopt theories, and draw wrong conclusions from them; but he shall not be able to burn the planetary system, nor even set this little world on fire,

OBSERVATIONS UPON DR. FORDYCE'S PAPER IN THE PHILOSOPHICAL TRANSACTIONS.

THE chemical philosophers have, for a long time, been labouring under the very extraordinary idea, that water is compounded of inflammable and pure airs. This must have originated from their misconstruing their own experiments. An idea, which, when maturely considered, bears evident marks of absurdity. For, in pursuing this opinion, the Royal Society is brought to believe, that the water of the river Thames has been set on fire,—

nay, that it thunders in its combustion.* That water should be deposited, when inflammable, and pure airs are fired, is perfectly agreeable to my fystem; which supposes that all airs have water for their basis, water being similar (as I have before shewn) to the water of composition and chrystalization in the neutral falts. Dr. Fordyce, who for accuracy and ability as a chemist, deserves the greatest attention, has given to the Society a paper, proving that the additional weight gained by the calx of zinc, above its metallic state, is certainly given to it by the water employed in the process. He says, in the volume for 1792, p. 382,-" And therefore the " matter occasioning the additional weight of the " calx, above that of the metal and the inflam-" mable air, are both produced from the water." In which conclusion we perfectly agree; but the most important question introduces itself, whether this additional weight is pure water, or a decomposition of the water? Most bodies are compounded; and to decompose them, you must do it by chemical attraction. The zinc made use of by Dr. Fordyce is (I suppose) formed of fixed fire, and an earth; by adding the vitrolic acid and water to the zinc, they decompound it, attracting its fixed fire, and the earth, the zinc requiring

their

^{*} See Dr. Pearson's paper upon the decomposition of fixed air:

their joint influence. It is just the same with lime fixed air and water. Lime has gotten a saturation of fixed fire, which the fixed air and water cannot set loose by themselves; but, by their joint powers, they can perform it, uniting with the calcareous earth, and expelling the fire †

The calx of the zinc, in the Dr.'s experiments, was united to the vitriolic acid and water; and, upon adding an alkaline falt to the folution, it united to the acid, from its fuperior attraction for it. But then the calx loofing one of its component bodies, would faturate itself with more of the water. Nay, we find that water alone, in the powerful state of steam, will form metals into calces; iron, for instance.

My fystem supposes, that the gravity of inflammable air is principally from water, with a little of the vitriolic acid and the earth of the metal, necessary to chemically attract and fix the fire.—Agreeably to Dr. Fordyce's accurate experiments, in nine grains of inflammable air, there would be two grains of the acid; as that weight of the acid disappeared: which is full as great a proportion as I thought it might posses.

Now, as the refult perfectly agrees with both hypotheses, (viz. the one generally received and mine) the only way to elucidate which is the true

[†] See a full elucidation of this doctrine in a paper of mine in the Gentleman's Magazine for 1792.

one, is to endeavour to afcertain, whether this additional weight of the calx is from pure air or. water. Inflammable air will precipitate the body which the calx is united to, forming water; but then, they fay, the water is formed from the union of the inflammable air and the pure air of the calx, which they suppose it to possess. I took strong concentrated nitrous acid, (what they call dephlogisticated acid) as free from water as possible, and added it to the calx of zinc, calcined and formed the fame, as in the Dr.'s experiments. As the earth of the calx has a stronger attraction for the acids than for the water, it would precipitate part of the water, if it possessed any. Upon adding the nitrous acid (but any of the mineral acids will equally do the fame) in fuch proportion, as to faturate the calx, there appeared a fensible moisture upon its furface; and to afcertain what that moisture confisted of, I exposed to the calx a strong heat, and I got a confiderable quantity of water from it. The calx was exposed to a fimilar heat, before I added the acid, and no water came from it. It retained its water by chemical attraction, and therefore the fire was not capable of expelling it. That water of itself will form metals into calces, by expelling their fixed fire, is not to be wondered at; for it will expel the fixed fire from the acids. When applied to fulphur, in the form of steam, it will unite with its fixed fire, producing inflammable air, as Dr. Priestley found.

That the moisture which came from the calx, upon its being united to the concentrated mineral acids, did not come from the acids, I ascertained by adding the same acids to earths, which possessed no water; lime for instance, and I got no water from them.

But to diversify the experiments of Dr. Fordyce: instead of adding the caustic alkali to the vitriolic folution of the zinc, let him precipitate the calx with the mild alkali; and the calx will be precipitated with part of the fixed air of the alkali. Now, if the calces of metals confift of the earth and pure air, by the addition of the fixed air to the calx of zinc in this experiment, it will weigh fo much heavier, according to the quantity of fixed air it got from the alkali; which is very wonderful. But I found the calx which was precipitated by the caustic alkali, (formed from an equal quantity of the metal) only twelve grains lighter, as that which was precipitated by the mild, though it ought to have been twenty grains lighter, from the quantity of fixed air which disappeared in the experiment.

But an experiment which I made fome time ago, before I read Dr. Fordyce's experiments, is a proof of this; viz. I took a dram of mercury, and calcined it in the nitrous acid, taking care to afcertain the exact quantity, and adding as much of the acid as was necessary to its calcination; I likewise carefully collected the nitrous air produ-

ced in the process. I then ground the calx with spirits of sal ammoniac, the nitrous acid left the calx, and united itself to the volatile alkali, forming the ammonical nitre; and accurately weighed the quantity it yielded. After this I took the same quantity of the nitrous acid, as I used in the solution of the mercury, and neutralized it with the spirits of sal ammoniac, and I got only about five grains more of ammoniacal nitre, than I got when the acid was ground with the calx. The loss of the acid I attributed to that which went to the formation of the nitrous air.

But, agreeably to Mr. Lavoisier's hypothesis, all the nitrous acid should have been decompounded into nitrous air and pure air; for, as I added no more acid than was necessary to faturate the mercury, so there should have been no acid left in the process: but the whole, appeared except what the nitrous air took up, which was rather more than the inflammable in Dr. Fordyce's experiment of the vitriolic acid; his being only two parts out of nine:-mine was in the proportion of three parts out of nine. But still to ascertain the refult with greater accuracy, I revived this calx of mercury, without addition, merely by the influence of the fire, and carefully attended to what came from it upon its reduction, and I found nothing but pure water. But, if the operator is not careful in receiving all the acid from the calx, there will be a little oxygen gas produced. That there

might

might no suspicion rise, that the calx got any inflammable air from the spirits of sal ammoniac, I used in the process the caustic fixed alkali, or the kali purum, and there was directly the same result; nothing but water appearing at the reduction of the mercurial calx.

I have repeated Dr. Fordyce's experiment. using the nitrous acid instead of the vitriolic, and iron instead of zinc, as zinc, with the nitrous acid, forms an imperfect nitrous air; and the refult was perfectly agreeable to my hypothesis: the nitrous acid was no more decompounded than the vitriolic, both acids being found entire: therefore these obviously plain experiments sufficiently refute the opinion of the acids being compounded bodies. But that my experiments may not be implicitly received, I refer the repetition of them to the accurate Dr. Fordyce: he has been bred in the old school, and I hope will not too hastily receive the fingular and hostile (I had almost faid monstrous) opinions, which are at present adopted by many.

OBSERVATIONS UPON DR. PEARSON'S PAPER IN THE PHILOSOPHICAL TRANSACTIONS.

Dr. Pearson's paper upon the decomposition of fixed air, comes next under our consideration.—
The variety of experiments made by the numbers

now employed in chemical pursuits, have given us a variety of phenomena; and the phenomena have been forced in, head and shoulders, to account for the very singular hypotheses now adopted. But I will make use of this bold affertion, that there is not one of their experiments, but finds an easy and rational explanation upon the principles of my system; while their explanations are in direct opposition to the phenomena. We shall find this observation to be verified in these experiments of Dr. Fordyce and Dr. Pearson.

The Dr. after giving us a history of affinities, which are a mass of strange contradictons, endeayours to take from Mr. Tenant the merit of being the first to decompound fixed air; saying that the chemical affinities are in opposition to his experiments, imputing the charcoal formed to the phofphorus; while the direct fame charge might be made to his. Those who repeat the Dr.'s experiments, will find very different refults. But the observations I have made from exposing the fixed alkalies and phosphorus to heat, are, that if the alkalies retain their water, the water acting upon the phosphorus will expel its fixed fire in the state of inflammable air. But if they are so far bereft of their water, that there is not sufficient to form the fixed fire into inflammable air, (which I have proved is necessary to the aerial forms) it will take the form of a kind of foot, the same as other phlogistic

phlogistic bodies will do, when exposed to fire; viz. coals, &c. when not actually ignited: which soot will unite itself to the materials employed in the operation; and which Dr. Pearson separated from them; for it, according to the quality of soot, will not mix with water.

Phosphorus, when burned in the open air, has fuch a tendency to ignition, that it will take fire of itself, and imbibe the water and fixed air, of which the atmosphere is formed. This shews that the phosphoric acid has a strong attraction for both these bodies. Therefore, these two bodies operating upon the phosphorus, under an intense degree of heat, while the alkali has a strong attraction for its acid, will produce a decomposition; the water and fixed air entering the phosphoric acid, and expelling its fixed fire. The observations I have made upon these experiments are, that if you deprive the alkali of too much of its water, it will not decompound the phosphorus so readily, the water aiding the fixed air in the decomposition. And if you leave the alkali with all its water, it will the more readily decompound the phosphorus; but then it is in that abundance, as to give an aerial form to the fixed fire, in the state of inflammable air.

That phlogistic bodies may be decompounded by water alone, we have many instances; steam passing through sulphur, iron, charcoal, &c.—But, as I elsewhere observed,* even in bodies which contain not an atom of fixed air, the phosphorus will expel part of its fixed fire, when exposed to heat, in the same manner as when it is united to lime. Nay, it appears by a gentleman in the correspondence of the Monthly Review, even when treated by itself, it will deposite this sooty matter upon its passage through glass.

We should not be surprised, if phosphorus is decompounded under this intense degree of heat, and surrounded by such an active body as an alkali. If sulphur be digested in oil of turpentine, and then slowly distilled for ten or twelve days, it will be converted into vitriolic acid, according to Homberg, M. P. 1703." Then need we wonder at phosphorus, which is a far more combustible body than sulphur, being decompounded, loosing its fixed fire in these experiments?

The black footy matter, which they call charcoal, is feen in other experiments, where there is an imperfect combustion, viz. in firing inflammable air got from metals and pure airs, there is often (as Dr. Priestley found) a deposit of this colouring matter, a part of the fixed fire of the inflammable air being not set free. But I should suppose they will not argue that this metallic inflammable air possesses any charcoal; but its appearance is accidental, depending upon the per-

^{*} See the Gentleman's Magazine, 1792.

fect or imperfect combustion. That it is not charcoal, is clear; indeed the giving it a serious discussion appears to me ridiculous. If any chemist will seriously consider the tests that they put it too, it will appear plainly that it is this sooty matter I speak of.

To shew how warmly a favourite hypothesis will be supported, Dr. Pearson acknowledges he got the same foot from the caustic alkali; but then he has this salvo, that he could obtain no alkali but what possessed some fixed air. But if he will look sharp, he may procure some that possesses not an atom of fixed air; nor will produce any when added to acids; which is a certain test. And which caustic alkali will, with phosphorus, produce this sooty matter; but, by, adding a very little water to the alkali, the least being sufficient, so as to assist in the decomposition of the phosphorus, though not enough to give its fixed fire an aerial form, but only this sooty one: they will together produce it.

The Dr. fays,—" I am very fully aware that the proportion of respirable air and charcoal produced in this experiment, do not correspond to the proportions of them, we should have expected confistently with the synthetical experiments concerning carbonic acid. The variation is especially great with respect to respirable air, of which there should have been eighteen grains instead of five, to combine

combine with the whole of the charcoal." Indeed, his experiments and deductions are fuch a confufed mass of inconsistencies and false conclusions, that Sir Joseph Banks, I should suppose, cannot clear himself to a learned and candid world, from the charge of partiality, in receiving his paper, and rejecting mine. Even these five grains of pure air, which the Dr. speaks of, is only supposed from their theory, as the phosphoric acid is formed in a small degree, and it is supposed to be formed from pure air.

But the following is an experiment so obviously clear, that it is impossible to mistake it. Take pure distilled water, and impregnate it with as much fixed air as it will take up in solution, marking the quantity absorbed, then expose them to the rays of the sun for some time, after which expel the air from the water by sire, and you will find a quantity of pure air formed. That it is the fixed air which formed the pure air, is certain, as a great proportion of it disappears in the experiment.

Dr. Priestley says, vol. II. p. 219, "In order to be more fure of this fact, I was more especially careful, the second time that I made the experiment, to use every precaution that I could think of, in order to prevent any error in the conclusion. For this purpose, I took rainwater, and boiled it about two hours, in order

** to get it perfectly free from air; and I began to " impregnate it with fixed air a long time before " it was cold, and therefore before it could have " imbibed any common air; and, in order to ex-" pel the air from it, I put it into a phial, which " I plunged in a veffel of water fet on the fire to " boil, taking care that both the phial containing " the impregnated water, and the glass-tube thro' " which the air was to be transmitted, were com-" pletely filled with the water, and no visible par-" ticle of common air lodged on the furface of "it. I also received the expelled air in water, " which contained very little air of any kind, left " the very fmall degree of agitation which I made " use of, in order to make the water re-imbibe the " air, should disengage any air from it. Also, " that less agitation, and less time, might be suf-" ficient, I chiefly made use of lime-water for this " purpose. But notwithstanding all these precau-"tions, I found a very confiderable refiduum of " air, not less than Mr. Cavendish had stated, that " water would not imbibe."

Now, can either of these experiments be reconciled to the new theory? Yet they are simple and plain; no crucibles or gun-barrels to look through. Upon the fixed air forming pure air, a quantity of charcoal ought to have appeared; and as the black colouring matter is the great characteristic of charcoal (agreeably to the decompounders of fixed air)

we should have seen the most minute tinge in the pellucid water: but it continues through the operation persectly pellucid and transparent.

Now, this simple experiment of Dr. Priestley's is positively only to be accounted for by my system, as being in direct opposition to all their opinions. Here is a quantity of fixed air turned into phlogisticated air, clearly and obvioufly, beyond the most vague conjecture, to suppose to the contrary. There was nothing but fire and water that were employed in the process to produce the change. It cannot possibly bear any other explanation than this, that the fire faturated itself with the fixed air and water, fo as to take off the aerial acid's acidity; but not to give it an impregnation or faturation of fire fufficient to form pure air, which the fire of the fun, operating by flow degrees, gives it, producing pure air. Their present hypothesis supposes phlogisticated air an element, and that fixed air and water are not formed of it.* From whence does it come then? Here one body disappears, and another appears, agreeably to the proper proportions. Will no admonition of mine call forth that candour and reason that ought to take place in philosophical disquisitions? I call upon an expla-

^{*} Dr. Priestley, from his late experiments. thinks that phlogisticated air is formed from an acid and phlogiston. Here, believely to the senses, fire produces the same effect.

nation of these two simple experiments. What must the candid world think?

Mr. Lavoisier, by an experiment, attempts to prove, that charcoal is one of the constituent parts of fixed air; which is this, by burning charcoal in pure air, a very fmall refiduum of the charcoal is left; while there is a large quantity of fixed air formed, nearly equal to the weight of both the pure air and the charcoal. But if we will confider what pure air is formed of; of the aerial acid and water, neutralized by fire; and charcoal of the vegetable acid, water, and fire, † part of which fire is so united to the acid that, upon cumbustion, it forms the aerial acid, commonly called fixed air. That in forming wood into charcoal, the heavy earthy parts go off united to the heavy inflammable air. Dr. Priestley even found the heavy earths of metals intermixed with nitrous airs and inflammable airs; and that, upon standing over water, they would deposite a part of their earth.* And he likewise

* Magnesia, by calcination, looses part of its earth. See Bergman's Essays, vol. I. p. 42.

[†] The immortal Scheele fays, p. 182,—" The charcoal is "most proper for the purpose, since it is a sulphur compounded of phlogiston and aerial acid. If coals be ground together with alkali, made caustic by quick-lime or fire, and then distilled in a glass retort in an open sire, a great quantity of inflammable air is thus obtained, containing no aerial acid: if a bladder be tied to the mouth, the alkali on the other hand "loses it causticity, and effervesces with acids."

found that the nitrous acid mixed with spirits of wine, &c. and aerilized, would be formed into the aerial acid; need we wonder then at the quantity of the aerial acid being found in the burning of charcoal along with pure air, formed from nitre, &c.

Can we have a more convincing experiment of what charcoal is formed of, viz. in passing the steam of water through charcoal, which forms two kinds of airs, fixed and inflammable airs. The vegetable acid of the wood, by being charred, having got a saturation of fire, in one case to form inflammable air, and in the other fixed air; the latter being a saturation just sufficient to give the acid a permanent aerial form. The steam giving to both the airs the water for their aerial composition.—This is the true explanation, without running into the wild supposition of water being formed of both these airs.

Even acids are separated from alkaline salts, by the influence of actual fire; and every chemist must allow, that there is a strong attraction between those bodies; therefore we need not be so wonderfully surprised, if phosphorus can be so decompounded. That neither it nor sulphur can be decompounded by heat alone, without the aid of other bodies, is most probably owing to the volatility of phlogiston. This is exemplified in alkalies. The fixed alkali can be bereft of its aerial

by lime, the volatile alkali cannot. But by lime, the volatile alkali is as foon made caustic as the fixed alkali. That, by the powerful influence of fire, both falts are sometimes aerilized with acids, appears from nitre being formed into air, from nitrum flammans the same.

In forming the calcareous earths into lime, in attending to the process accurately, we may obferve different phenomena; at first the fixed air and water are expelled, and the earth faturated with loofe fire. But if you push the process farther, the fire will, instead of taking this loose faturation, become more fixed, penetrating the earth, fo as to become alkalescent: and in this state, the lime becomes light and spungy, having lost part of its earth, and will not do for mortar. the workmen rejecting it, as being useless: for it will not split and fall into powder with water .-I have, by carrying on the process for a long time. made it almost an alkaline falt, turning it perfectly mild, in respect to its causticity, and having the properties of alkalies in most of its qualities.*

Dr.

^{*} I have proved, in my Thoughts on Air, that the causticity of lime does not depend upon the absence of its fixed air, but upon its saturation of loose fire; which fire, when it becomes active by water, &c. burns or consumes bodies. Now, this experiment proves it: for, when the fire is so pushed in the process, as to be more fixed in the earth, so that moisture, &c. sannot expel it, the lime then becomes mild;—and it will bear

Dr. Pearson's paper mentions a redish brown powder, which he obtained from lime and phosphorus; and which, upon being thrown into water, produces a vapour that fulminates with the atmosphere. This fulminating vapour, agreeably to the present hypothesis, decomposes the water. Need I mention that the fire, which the phosphorus and lime receive, and being fo exficcated, that, upon coming in contact with the water, they imbibe or attract it; and fo much fire is fet loofe from the lime, &c. which, along with the water, aerilizes the phosphorus; and probably may set a part of its fire loofe, as inflammable air, as there is plenty of water to give it an aerial form: and not the very fingular and extraordinary idea, that the water is decompounded; and, upon its ignition, it thunders. How long will our modern chemists go on with their experiments to support such hypotheses? Human knowledge is weak; and in the inveftigation of abstruse subjects, very weak opinions have been received. This we see often exemplified. But then, when a regular fystem has been offered, which embraces all the phenomena; for I must again repeat, that there is not one experiment of

no other explanation. The idea of its wanting its acid to neutralize the earth, is quite inadequate to the phenomena; for it ought in this case to have become more caustic at the latter part of the process, instead of its becoming perfectly mild, and of an alkalescent quality.

the many thousands that have been made, which my doctrine does not fully and rationally account for. Then what must we think of our chemical philosophers, who so far from receiving it, take every method they can to suppress its investigation. Though they have not published against it and abused it; yet their treatment has been more cowardly and fhameful: they have allowed the reviewers, those traders in criticism, to brand it with all the abuse they can; while they never once offer publicly to investigate it; well knowing, that to bring it to public notice, would be to establish it: therefore they stand in the eye of justice, candour, and liberality, in the same predicament, as if they themselves had so shamefully abused it, -indeed it would have been a more manly part. This kingdom is marked for its liberality and candour; but I am afraid we have our aristocrats in science;—yea, even those men who are bawling most for liberty, vulgarly called patriots: but the word implies a liberality and generofity of fentiment throughout.

As the forming fixed air into dephlogisticated air, is certainly a process by which we may accurately judge of the formation of dephlogisticated air, I have paid a particular attention to it; but I will not give the minutiæ of the experiments, as many have done. If the public, after the usage I have received, gets a detail from me, they may be

fatisfied. To other philosophers the philosophical Transactions are open for their long history of dry experiments: but I hope the day of reckoning and retribution will come. That fixed air, when soluted in water, will, by the action of the sun. form pure air, has been proved by Dr. Priestley and others. As my theory supposes that fixed air and water, united to the rays of the fun, will form pure or respirable air; therefore, to shew whether my theory or Mr. Lavoisier's is just, I made a number of experiments. I took fresh distilled water, and exposed it to a strong heat, without getting any kind of air from it; I then added to it a quantity of fixed air, which it readily absorbed, marking the quantity; after that, I exposed it to the rays of a hot sun. But as transparent bodies are well known to admit the rays of light to pais through them, without arrefting or stopping their passage, I added an extraneous body; any will answer, filk thread, or a dead leaf, dried straws, &c. which have an attraction for the air; and by this means I found a great quantity of pure air rise to the top of the decanter, which contained the water; after that I expelled all the air from the water by heat, and I obtained rather a larger volume of pure air, than of the fixed air used; and not an atom of the latter-I found that two things were to be attended to in those bodies, which were added to the water, to affiff

affift the process; viz. they ought not to be transparent, and ought to have a kind of an electrical repulsion to water, so that the air may stand upon them in distinct globules: I found glass bodies, for these reasons, improper, and likewise linen thread, which had a great attraction for the water.

It is remarked by philosophers, that green animalcules appear when the water gives out air in the greatest abundance. This appears to be from their arresting the sun's rays, and attracting the air in the water, the green seeming to be the best colour; and which nature indeed, makes use of in the great vegetable world, in attracting the rays of the sun. When these green animalcules appear in the water, by gently adding fixed air, you may continue on, for a long time, the process of generating pure air.

The globules of air, when they are feen standing upon the filk, &c. appear little at first, but gradually grow bigger; the filk reslecting the rays, and by that means they enter the globule, warming it, and saturating the air, growing larger, and as it were generating or forming pure air, by the fixed air attracting the rays, and saturating itself, by neutralizing them along with the water. We see most of the saline productions of nature are formed of acids, an alkaline salt, (which I suppose sixed fire) and water, and forming regular crystals. In the vegetable kingdom, most of the bodies belonging to it are formed of acids, fire, water, and

earth; in bitumens, oils, &c. a more concentrated fire is necessary with acids, fire, water, and earths; and the different concentrations, combinations, and proportions of these bodies make the different bodies upon the earth, without running into the wild speculative opinion, that all bodies are formed of airs. No airs are formed of them.

But even our philosophers have given very different opinions upon the origin of fixed air. Dr. Austin, whose experiments certainly deserve the greatest attention, formed fixed air, where there could not be the smallest reason of supposing there was any charcoal in the process; so he, from these experiments, formed an hypothesis that fixed air is formed from inflammable air, phlogisticated air, and pure air. But these experiments of his are to be explained upon my fystem. When pure air is fired with the pure inflammable air of metals, the fire is fo intenfe as even to take from the acid its aerial state, as fixed air, and forming it into a condensed acid. But if pure air is fired in the heavy inflammable airs, from charcoal, oils, &c. the ignition will not be fo intense, and the acid will still keep its aerial form.-Now, here is the doctrine of fixed air, both by analysis and synthesis. If the nitrous acid is added to an alkali, or a calx, and exposed to a strong heat to aerilize them, they will form pure air; and if this pure air is burned in the heavy inflammable mable air, the pure air will be formed into an aerial acid: but if fired with a purer inflammable air, the pure air will be formed into the nitrous acid it was made from. Nay, still stronger, if this pure inflammable air is gently added to pure air, so that the ignition is not so intense, the acid of the pure air will still retain its aerial form, viz. the aerial acid. This Dr. Priestley sound, when he exposed zinc and turbith minerial to a strong heat.† And even

† Dr. Bewley fays, p. 65,—" With respect to the com"bustion of inflammable air, sulphur, phosphorus, &c. Mr.
"Lavoisier hath given some accurate experiments, which prove
"the heat to be very considerable; but the heat, when fixed air
"is produced, is considerably weakened in these combustions.
"The difference is, indeed, very great; but it seems evident
"that that must be owing to the intensenss of the combustion,
"and not to the particular ingredients burnt; as the same bodies
burning produce the different residuums. In burning inflam"mable and oxygen gas, the fire is so intense, as to burn instantaneously, going off with a loud explosion; but when
these two bodies burn in a slow and gentle manner, they form
only fixed air. To prove this, Dr. Priestley has given many
"experiments, and indeed, the proofs from them are very good
"ones.

"Ones.
"But then, that his experiments may correspond with his
"very singular doctrines, he supposes that the fixed air is pro"duced from the dephlogisticated air, by imbibing inflammable
air in its nascent state, as he expresses it. To make the ex"periment, expose zinc, iron, red precipitate, turbith mineral,
"to fire in earthen retorts: and the process is simply this; the
"combustion takes place in a gentle manner, as the dephlogis-

even those inflammable airs which form pure air into the aerial acid, if they have a greater quantity of fire thrown into them by the electrical spark, fire, &c. so that in the combustion a more intense heat is produced, they will condense it

"ticated and inflammable airs are generating; for, as the heat produces these airs, it will in consequence ignite them. That it is from this simple cause, is beyond all doubt; for, if you take care not to raise the heat so high as to ignite the airs, you will receive them both entire. Dr. Priestley was bassled in many of these experiments, owing to their firing with an explosion, after a quantity had been generated; however, he often produced them quite separate; which he could not have done, had there been (as modern chemists would have us bestieve) great attraction between the two airs. Now, these experiments are in direct opposition to Mr. Lavoisier's doctrine; for there is fixed air generated, when water only ought to have been generated; and there was positively no carbone.

"Nothing can more clearly establish our hypothesis, namely, that the quality of the residuum, after burning these airs, demends upon the intensens and degree of the combustion; for if a column of these two airs goes off instantaneously, here all the fire which these two airs possessed, acts at one and the fame time, and must produce a considerable quantity of heat. But in those processes, where fixed air is formed, it burns in a gentle and gradual manner. What shows this in a most firking light is, if the instammable air from the wood is fired with respirable air, it burns more gradually, so as to produce fixed air. Yet, if this same instammable air has a greater quantity of fire thrown into it by the electric spark, or common fire, it will explode all at once, just as the instammable air from metals does, and produce the nitrous acid."

into the original nitrous acid. Nav, even the fixed air, which is formed by water and the fun into pure air, and that fixed air, which is formed into pure air by exposing the calx of mercury, (made from the corrofive fublimate, decompounded by the fixed alkali) will, if fired with the inflammable air from metals, be found in the state of the nitrous acid, as Mr. Cavendish found. I have found that those inflammable airs, which will form pure air into fixed air, if they are mixed and pass through a red-hot gun-barrel, will burn fo intenfely, as to form the nitrous acid. The learned and ingenious Dr. Milner, by paffing the volatile alkali through manganese, found nitrous air formed. As the process was conducted in a redhot gun-barrel, and as the manganese generated the pure air, it fet fire to the volatile alkali, and the combustion was conducted so intensely as to form the pure air into the nitrous acid and water; both of which acting upon the phlogiston, either the unburned volatile alkali, or that of the iron of the gun-barrel, produced nitrous air. Can philofophical chemists wish for more clear and self-evident demonstrations? They ought not to run into those wild conjectures of water being formed of airs; and of charcoal and pure air, forming fixed air. Charcoal is a factitious body.

OBSERVATIONS ON DR. BEDDOES' PAPER IN THE PHILOSOPHICAL TRANSACTIONS, ON THE PRO-CESS FOR CONVERTING CAST INTO MALLEABLE IRON.

Dr. Beddoes has endeavoured to explain, upon the principles of the new theory, the phenomena of this process for converting cast into malleable iron, in two papers which are published in the Philosophical Transactions. It is an explanation embarraffed with difficulties; for, according to the principles of this theory, it is supposed that pure air is necessary to the process, in uniting with the charcoal, and discharging themselves as fixed air. But the Dr. fays,-" Its action upon the " metal feems to be pernicious: I confider its " prefence as an evil." Now, if Mr. Lavoisier's theory be true, it would certainly greatly haften the operation, by discharging the charcoal. But without following Dr. Beddoes in his experiments and observations, which being conducted under the influence of this theory, are contradictory and erroneous, I shall give the history of the phenomena, as I have observed them, explaining them upon my theory, and then we will fee which more fatisfactorily accounts for them.

I suppose that the cast iron is only imperfectly metalized, and still retains part of the charcoal

again applied, the ingredients begin to attract the fire of the charcoal; and, as they attract it, they give out the water they were united with: for most of the metals are found in the bowels of the earth in their state of calces. I have found, that these calces are formed from the earth of the metal being united to the water, and not to pure air. My process, in proving that, is (after carefully taking sulphur and all extraneous bodies from them) by adding a concentrated acid to them, and then by exposing them to a great heat, I get water from them.—See page 24.

Then, upon the water being separated from the calx, will act as fteam, from the influence of the fire, and form part of the charcoal into inflammable and fixed airs; the workman stirring the ingredients which affift the operation, that all parts may have the influence of the heat, and each particle come in contact with the charcoal. One very striking phenomenon is, that a great heat will be generated, apparently from the ingredients themselves, and not from the influence of the fire: and this, I have observed, is the time when the process is most active, the calx receiving the charcoal's fire, and the iron becoming malleable. It is the fame in the calx of gold, when it fulminates with the volatile alkali. The calces are then decompounding the alkali

and charcoal; making the fixed fire of the alkali and charcoal become free fire, the calces taking or attracting it from its present chemical combination, uniting with it, and they becoming metals. But, in this operation, a great quantity of the fire becomes active, and escapes. This process, as I have observed, is clearly seen in the calx of gold: the calx penetrating the volatile alkali, attracting its fixed fire from its combination with the alkali, and seizing a great part of it, becomes gold; while a great quantity of it escapes as actual fire, forming the explosion.

In the process of the iron, when the calx is attracting and setting free the charcoal's fire, there will be at that time the greatest generation of airs: for the water of the calx of iron being expelled by the fire, it will be formed into steam, which will act upon the undecompounded charcoal, forming inslammable and fixed airs.†

Now, these phenomena are not to be accounted for by their theories; but mine gives a full and satisfactory explanation of them; indeed they are its strongest evidence. And it explains a

† For I have found (in the process of passing steam through charcoal) that when the charcoal was not exposed to so strong a heat, and the steam in the greatest abundance, that the greatest proportion of fixed air came over; and when great heat and less steam, more instammable air.—See my Letter to Dr. Priestley and others.

phenomenon which was always perfectly obscure, how phlogistic bodies, (bodies which possess a great quantity of fixed fire) reduce metals. It evidently appears it is not from their uniting to the calces in their compound state; nor in the state which Stahl supposed, but in the state of actual fire: and that this fire, at the time, is excessively intense, heating the whole mass considerably. And it is a well afcertained chemical fact, that a body, at the time of its difunion from another body, which difunion being by the influence of chemical attraction, will, from this chemical attraction, rush into the attracting body, and chemically unite itself to it, far more fo than if the actual fire was applied from a common fire in an elaboratory.†

There

† Dr Beddoes mentions a phenomenon, which, I think, corroborates my opinion of the formation of inflammable and fixed airs from charcoal; that when the process was almost finished, and when there was little moisture and great heat, there only came over inflammable air, and no fixed air comparatively.

Dr. Beddoes, in his book upon Mayow, fays, p. 51,—"Now let the pieces of iron be let down into the nitrous acid, by loofening the cord, when a violent effervescence, accompanied with heat, will arise, and the water within will be depressed by the generated gas.—When the effervescence has continued about twenty minutes, or rather when the water has been depressed about three singer's breadth, the iron is to be raised out of the liquor: you will now soon see the water within ascend gradually, and in an hour or two it will stand far above

There is a very striking phenomenon, viz. when iron is hammered, it becomes red-hot, and takes fire. Now I do not see how the new theory can account for this sact; how hammering should make it imbibe pure air. But, in driving a nail into the firmest wood, the phenomenon is the same, where the atmospheric air is excluded. The same phenomenon takes place if you rub two pieces of wood together, they will take fire; and, previous to their taking fire, they become charred. In this experiment, they suppose the pure air not necessary in charring; then why necessary in the

"the mark; for having been at first depressed three singer's breadth below, it will be now as much above the mark; so that about one-sourth of the space occupied by the air will be filled with water: "and indeed the water thus elevated will descend, in no long time, to its former level." I suspect some mistake here: the author says nothing more of this strange new depression of the water: how can any air be generated in these circumstances? Did one of the pieces of iron at any time come off the bunch, and remain behind in the acid? I wish the passage were out of the book, or at least, that some one would explain it to me."

Now the explanation appears to be clearly this, upon taking the iron out of the nitrous acid by the cord, the iron was still in a state of generating more nitrous air; therefore, after the pure air was fully acted upon by the nitrous air already generated, taking the iron out of the acid at that part of the process, its surface being covered with the acid, they go on generating more nitrous air; and in consequence increase the volume of airs.

process with the iron? I think there is no doubt, but both phenomena are upon the same principle. I rubbed two pieces of wood inclosed in a bladder, containing, in one experiment, azote, and in the other the aerial acid; the bladder being only one third filled with those airs: so that I had liberty to hold each piece of stick so tight, as to give them the attrition necessary: and the same phenomenon took place, as if they had been rubbed in the open air: they became charred. If a piece of fir is exposed to the influence of the dephlogisticated marine acid air, it will be charred, the acid feizing upon the fir's phlogiston; and, in the attrition, the wood likewife loofes its phlogiston, escaping as actual fire. Now, in charring wood, every chemist must know the process, and what comes from it, when charring, feen by placing the wood in a gun-barrel, and exposing the barrel to a great heat. In the operation, a confiderable quantity of inflammable air comes from it; and in iron the same. To char it, it is necessary to take away the inflammable air from it. Then, in these two processes of attrition and the application of the dephlogisticated marine acid, the wood must have lost its inflammable air; which is really the cafe.

But let us attend particularly to the process of inflaming iron, by taking from it its inflammable air or phlogiston; or (to speak with greater proE 2 priety)

priety) its fixed fire, by the power of mechanical friction.

I got a large piece of buckram, and glazed it, fo that it was impervious to the air; I inclosed within it a small smith's anvil, and a rod of iron; in one part of the cloth there was a hole, fo as to admit a fmith to put his arm into it, and then the hole was tied very close upon his arm, so as to hinder the passage of any air, and the buckram was pressed close, so as to press out any air; then I filled it again with fixed air, passed through a heated gun-barrel, to exclude any moisture, all the apparatus being extremely well dried for the experiment; after that I pressed out all the air, in order that if any atmospherical air had been left. it might be expelled, and filled it with pure dry fixed air.* I defired the fmith to hammer the iron; taking hold of it with his left hand, through the canvals.

After he had struck it for a long time, I carefully examined the rod, and particularly the particles that had been struck from it; and I found that part of the rod which had been hammered, and the grains that had been separated from it, had lost,

^{*} There was an affiftant to keep the fides of the buckram from interfering with the hammer; and likewise a little window formed of glass, and glewed to the buckram, so as to aid the artist in striking the rod of iron, which became very hot in the operation.

in a great measure, their malleability; to the eye they appeared nearly as if they had been calcined in an open fire. I found that the magnet that bore a dram weight of the iron, cut into similar pieces, and inclosed in a piece of paper, would not bear above half a dram of those that had been calcined in the experiment. That a diluted solution of the vitriolic acid produced nearly twice as much inflammable air, from that part of the iron rod which had not been hammered in the experiment, as from that which had; and that a small quantity of fixed air came from the calcined iron. You will find the same result, if you employ in the experiment azote instead of fixed air.

This experiment will be more easily performed, if you have a small iron mortar, fixed in a smith's vice, and a very heavy pestle, such as the apothecaries use, with a bladder well dried, and filled with fixed air, and tied close to the top of the sides of the mortar, and round the lower part of the pestle, so as to admit of the pestle's motion, about four inches up and down, and pieces of iron being put into the mortar, and forcibly beat and ground for a long time.

Now here was a great heat generated, and a very fensible loss of the iron's metallic principle, without either pure air or water being employed in the operation. I employed fixed air, as it is well known that it extinguishes red-hot iron im-

mediately; that so far from conducing to its combustion, it has a striking effect in extinguishing it.

An idea has been entertained, that fire is owing to the vibration of matter, and not to the action of a peculiar fluid. This was the opinion of Sir Isaac Newton; he was no chemist; but had he traced fire in the different chemical processes, he, no doubt, would have deferted the opinion. I think with Bergman, that there cannot be a clearer fact, than that fire is produced from a certain material substance. He fays, vol. I. p. 36,-" Numberless phenomena, which we cannot here " confider, evince, beyond a doubt, that heat is " the effect of a certain material substance.—It is " fufficient here to observe, that subtile matter of " heat occurs in two distinct states; either it is at " liberty, in which state it pervades all bodies, so "that all attain the same temperature, or it is "fixed by attraction, and does not exhibit sensible "heat, unless set free by more powerful attrac-"tion." I think there is no philosopher who has attended to chemical phenomena, but must be of the same opinion. But here I have given experiments, which prove, beyond a doubt, that fire is a certain material substance, and which material fubstance in the iron and wood was in the form of inflammable air; but, by the mechanical friction, was separated from its chemical combination, as actual fire. We have many instances

where

than

where mechanical compression can set free actual fire. A very simple one is in Dr. Darwen's experiment on atmospherical air; by the compression of it, he produced heat, and, by expanding it, he produced cold. I would have philosophers attend to these experiments; I think they sully prove my system of sire.

Dr. Fordyce's paper to the Royal Society, of heating the diaphragms of pasteboard and iron, only prove this, that metallic bodies, from receiving a certain quantity of fire, raife the temperature higher than some otherbodies do, by receiving the same quantity. This fact is most strikingly proved in Boerhaave's famous experiment of mercury and water; the water raising the mixture fo much higher than the mercury; though heated before the experiment to an equal degree. -The elucidation of which (fee my former publications) is from the mercury (and the iron from the fame cause) having already a high faturation of fire, (as phlogiston) which fixed fire will act upon the actual fire, though fixed, raifing the temperature; and when mercury, or iron, is cooled, they will give out less fire, because part of this fire is fixed; but, nevertheless, this fixed fire will, in a fmall degree, act upon the actual fire as actual. This, as we have just observed, is strikingly feen in mercury; a pint of boiling water will raise a pint of mercury so much higher

E 4

than it will do a pint of water of the same temperature with this mercury; but take away the mercury's fixed fire, or phlogiston, by calcination, and the water will not heat it so much.

Steel is only iron, which has received a higher faturation of fixed fire, than iron. The process of making it being in exposing iron to phlogistic bodies; or in heating iron red-hot, and then hastily extinguishing it in the cold water. The iron's fibres being distended with the heat, upon the mechanical application of the cold water, are suddenly contracted, and, in this contraction, fix the fire. The same as the fixed alkali, by being mechanically agitated with fixed air, will receive a greater saturation of it, than it before possessed, having a superabundant saturation, as it were.

ON THE FORMATION OF PURE AIR FROM MERCURY.

That famous experiment of Mr. Lavoisier's, which is the pillar of their present hypothesis, viz. in calcining mercury, there is pure air attracted by the calx, and upon its reduction (without addition) it gives out pure air; the explanation of which is given by Dr. Bewley.*

But

^{*} Dr. Bewley fays, p. 92,—" The experiment which first fuggested, and is the foundation of Mr. Lavoisier's doctrine, appears

But in calcining mercury by agitation in water, I have found the mercury calcined, from the water alone, without any pure air. Dr. Bewley fays, p. 104,—" Dr. Harrington hath clearly "proved

"appears, upon the first glance, to be very much in favour of it; and he says, to prove it both analytically and synthetically. If mercury is calcined in atmospherical air, the air will lose its oxygen gas, being imbibed by the mercury; and, upon reducing the mercury, a quantity of oxygen gas will come from it; the mercury will be reduced, and the air become respirable again. Now let us investigate these phenomena, and see whether Mr. Lavoisier's theory, or that of Dr. Harrington, will best account for them.

"Mr. Lavoisier says, that the oxygen gas is a pure element. " Dr. Harrington fays, atmospherical air is formed of fire, fixed " air, (or, as Mr. Bergman, with greater propriety calls it, the " aerial acid) and water; but the factitious oxygen gas of fire and " acid, water and earth. Now Mr. Lavoisier allows that the " calcining of metals is an act of combustion, which is strikingly " feen in the calcining of iron by burning. And Mr. Lavoisier must also allow that, when most bodies are burned in atmos-" pherical air, the oxygen gas turns to the aerial acid or fixed " air; and that, into whatever this oxygen gas is turned in the "burning of mercury, it is imbibed by the calx. I should ex-" pect, that Mr. Lavoisier will allow me to suppose, that the " combustion of one body is much the same as the combustion " of another, (just as the respiration of one animal is like to "that of another) that is, acts the fame upon oxygen gas. "Then I will suppose that the burning of the mercury, and " most of the bodies, upon this earth is the same, and that they " all turn oxygen gas to an acid air. In one cafe only, the so oxygen gas is not imbibed by the burning body, but in the " other

" proved the following facts; namely, that the calx of iron, made by fleam, is formed by the calx imbibing the pure water; and that the calx of iron, formed by burning it with the oxygen gas, is from its imbibing the acid and water contained

" other it is. Then let us suppose that this fixed air, or aerial "acid, is imbibed by the calx of mercury. That the calx of "mercury has a great attraction for air, is a fact which has 46 been long known in chemistry. I will give Mr. Lavoisier an "example. The corrofive fublimate, of mercury, if united to " an alkaline falt, the fal absinthii for instance; the marine " acid will leave the calx of mercury and unite itself to the " alkali: and the fixed air of the alkali will unite itself to the " calx of mercury. This experiment is well known to chemists: " and it is equally as well known, that if this calx of mercury is " exposed to heat, it will form oxygen gas, and the mercury "will be reduced. Dr. Harrington fays in his Letter, p. 88. "But even fixed air may be formed into pure dephlogisticated " air, if united to the calx of mercury (this calx we have all " along proved to have the greatest attraction for concentrated "fire) viz. in the experiment of the corrolive sublimate being " decompounded by an alkali; if exposed to fire, it will yield " more empyreal air; but it cannot bear the explanation that "Mr. Kirwan gives of it, viz. the fixed air being decompounded; " for if the fire is not pushed, you will get the dephlogisticated " air from it, and the calx will not be reduced: nay, to shew 44 that it is not phlogisticated after this process, agreeably to Dr. " Prieftley's own test, it will form with the nitrous acid, pure "dephlogistigated air again; or if united to the marine acid, " and then precipitated again with the alkali, it will form again of pure dephlogisticated air. Our theory here appears so rational, 66 that

"tained in the gas: but nothing but pure water
"is found in the calx made by steam. I have
"likewise found, that the calx of mercury,
"made in distilled water, by strong agitation, (a
"mill,

"that, when this dephlogisticated air is burned, it will be decompounded; that is, its fire will be separated from the fixed air,
both being produced in the process of burning."

"Now, it is evident that Combustion, or the setting loose a quantity of actual sire, has the power of turning the oxymen gas to an acid; and we must suppose that the aerisal acid, when condesended in the Mercury, must become concentrated, forming an acid of much greater acidity. That fire will turn the pure part of atmospherical air into fixed air, has been fully shewn in this treatise; viz. the electrical spark taken in atmospherical air; and it will also turn oxygen gas into the nitrous acid. It has likewise been provived, that when nature's oxygen gas of the atmospherical air, and the factitious oxygen gas of chemists, are operated upon by pure fire, (see p. 84 of this Treatise) that they will be turned to the nitrous acid.

"Then we are clearly brought to this conclusion, that acids and the calx of mercury produce oxygen gas; and what directly confirms this conclusion is, that if an acid, either of mitrous, vitriolic, or fixed air, is added to the clax of mercury, they produce oxygen gas.

"Chemists say, that this production of oxygen gas, is from the oxygen gas, which they suppose the acids and the calx possess. But with respect to those other bodies which are faid to possess oxygen gas, try if they will produce oxygen gas with the calx of mercury; and steam, as they say, is capable of decomposition; then water (for instance) seems to be the most proper body, as containing the greatest quantity

"mill, for instance, one of Dr. Priestley's experiments) will give out no oxygen gas, but pure
water only, at its reduction, (when it is reduced
without addition) and yet Dr. Priestley has
proved

"of oxygen gas: and likewise the calx of mercury has a strong that attraction for its inflammable air. Water then, conformably to them, should be the most proper for the calces to get oxygen gas from: and therefore the properest body to unite to the calx of mercury: but it will not answer to unite the calx to this or to any other body, but only to acids.—
"Moreover, what strikes directly against their hypothesis is, the factitious oxygen gas is fully proved by Dr. Harrington, to be a different kind of gas, from the pure part of atmosphesical air.

"Then, in this case, we must be allowed to say, that the bodies, necessary to produce oxygen gas, are an acid, the calk of mercury and water. It is well known that acids and the earth of metals have a strong attraction for each other; and these two bodies have a strong attraction for fire or phlogistion. The nitrous acid, by being exposed to a great heat, becomes red and phlogisticated; and the calx of mercury has so strong an attraction for fire, that heat alone will reduce it. And, as to phlogistion, the nitrous acid has so very strong an attraction for it, that chemists have placed these two at the head of the table of attractions; and the calx of mercury greatly attracts phlogiston and becomes reduced. It is no less true that heat will aerilize both the nitrous acid and the mercury.

"Now, under a review of all those circumstances, are we not authorized to suppose that, when these bodies, the acid, the calx and water, are for a long time exposed to a great heat, that they will fix a quantity of this heat or fire, and be aerilized with it, forming that neutral phlogisticated body, called oxy-

" proved it to be a calx, viz. the precipitate per se.

" See Priestley, vol. IV. And I have also found,
" that, at its reduction, it imbibes inflammable air,
" and is a calx similar to that made from iron by
" water."

"gen gas? The action of the fire implies this; for when they become red, they give out only empyreal air: and it is very well known that fire or phlogiston reddens the nitrous acid.

"That the acid gets neutralized with the fire and water, appears from Mr. Cavendish's experiments. This process is fill more evident in lead. If lead is burned in a quick way in atmospherical air, it will form only the grey calx of lead, as it imbibes the acid of the air in its reduction: and if the calx is exposed to a great heat, it will give back again only that acid. But if this lead is calcined in a gentle way, by being exposed to the reverberation of the heat, it becomes gradually red, till at last the red is highly florid, and of the same colour as the calx of mercury.

"That the calces become red from the fixed fire in them, is frongly confirmed by this, that their colour is fimilar to that which the blood receives in the lungs; this has been fully proved by Dr. Harrington, to proceed from no other cause, but receiving fire or phlogiston: and, what farther corroborates this opinion is, that alkaline salts, which I hope, I may now be allowed to call fixed fire, will produce the very same effect upon the blood, forming it into that high florid red colour; and oils the same.

" and oils the lame.

"That part of the mercury goes along with the acid, in forming the oxygen gas, hath been fully proved by Dr.

"Prieftley: this is still farther confirmed by nitre. Nitre is that body best adapted to form oxygen gas, an ounce producing half an ounce of oxygen gas. Now, alkaline salts are found to be already fire fixed and concentrated by nature;

"water." I fee, from the Analytical Review, that upon the continent they are making similar experiments. "The reviewer of Crell's Chemical Journal in the June Chronicle, having noticed an experiment by Mr. Gren, in which he received quickfilver calcined per fe, without obtaining dephlogisticated air, and requested him to repeat it, as, if confirmed, it would strike at the root of the new theory. Mr. Gren informs him, that it has been done more than once, by Mr. Westrumb, whose letter on the subject he transmitted to him. Mr. Westrumb put half an ounce of quickfiver, calcined per fe, into a small retort, with a neck three feet long: to this he luted a right angled tube, that terminated in a glass with two aper-

"therefore part of the process is already executed, the fire being already fixed: consequently, the acid and the alkali only want fire enough to aerilize them.

"What then must we think of that hypothesis, which sup"poses that a strong acid and an alkali can be separated after
"they are united, and they say, that by a supposed separation, and
"a supposed attraction, the acid is decompounded of its oxygen
gas and phlogisticated air. But where is their proofs that
alkalies have any attraction for phlogisticated air? They have
none. Nay, the most whimsical (or shall I call it absurd) part
of all is, (as Dr. Harrington has shewn, see p. 17 of this
Treatise) that Dr. Priestley got such a quantity of airs from
intre; that in one process the alkali must have attracted the
acid's dephlogisticated air, and its phlogisticated air in the
other process; and in both cases, both airs being nearly above
the weight of the acid: but enough of such absurdities."

tures, by means of which it was connected with the pneumatic apparatus. The lute confifted of gypfum spread on linen, over which several strips of linen, fmeared with a mixture of quick-lime, and curds were wrapped. The retort being placed in a crucible, and furrounded with fand, was exposed to the heat of a good wind furnace. It was fcarcely red-hot, when drops of clear water appeared in the neck of the retort: these gradually increased, and collected in the glass. They were followed by quickfilver, in its running form, without a fingle bubble of air making its appearance. Mr. Westrumb has made experiments on the subject in different ways, with calcined quickfilver and phosphorus, with the former and fulphur, and in other manners, and the refults are altogether contradictory to the modern fystem of the French chemists. Mr. Gren is now preparing the black calx of quickfilver, having inclosed a pound of quickfilver in a veffel fastened to the hammer of a fulling mill for the purpose, in order to make fimilar experiments with that."-Vid. Analytical Review, for August, 1792, p. 473.

I have found, that if you expose red lead, immediately after it is made, to a strong heat, you can get no oxygen gas from it. But, by being exposed to the air, so as to receive moisture from it, it will then give out oxygen gas at its reduction, as before it wanted the water necessary for its aerial state. And to prove that it was from that cause that it would not give out any pure air is, if you expose it to a strong fire in that state, (in which it wants water) you will reduce it, (without addition) but no pure air will come from it.

Now, it certainly is impossible to reconcile these facts to Mr. Lavoisier's system. The calx of lead ought not to become metallic, without parting with pure air: as this body is one from which he got pure air; indeed, it and the calx of mercury being the greatest pillars of his theory: for if you take the other calces of lead, the grey, &c. they will only give out fixed air at their reduction. They having not been exposed to the fire of a reverbatory furnace, to faturate the acid, (which it received from the air in its calcination) which is necessary to the formation of pure air. I am happy in feeing those experiments prosecuted on the continent, as they directly strike at the root of the new doctrine. My experiments are not attended to; but when they come from others, fuch as Mr. Westrumb, they are favourably received; truth must prevail. +

ON

† It has been found that the pure air, made from the calk of mercury and an acid, when breathed, possesses a quantity of mercury, so as to produce a salivation; though the air had been well-washed in water previous to its being breathed. Therefore, I think, this confirms my opinion, that part of the calk

ON ALKALIES BEING COMPOUNDED OF FIXED FIRE.

MR. Fourcroy found that alkalies, when united to the dephlogisticated marine acid, are capable - of being ignited, the fame as any combustible body. -- " When M. Fourcroy poured the " concentrated fulphuric acid on the oxygenated " muriat of potash, he observed a violent effer-" vescence, and the production of a white vapour, " which, though it resembled in smell the oxyge-" nated muriatic acid, had a character peculiar " to itself: the falt and the acid both became of "an orange colour. He then varied the experi-" ment, by casting some of the muriat into the "acid: the effervescence thus occasioned, was " fcarcely perceptible: but, when the mixture " was ffirred with a glass tube, a violent explosion " took place, accompanied with transient flashes of " red light; after this commotion had fubfided, a " fecond agitation produced another explosion not " less violent, and accompanied with more splen-" did corrufcations than the former. On bringing

goes to the formation of the air. The breathing of this air in confumptions, particularly those which have been supposed to have originated from a venereal taint, I should suppose would be advantageous. And likwife venereal patients, whose constitutions, from irritability, would not bear mercury any other way. F

"the flame of a taper near fome of the mixture, which had already made one explosion, white vapour arose from it in great abundance, and a detonation took place, which broke the vessel that contained it, and was succeeded by a number of partial explosions of the parts of the mixture which were dispersed to a considerable distance. A piece of phosphorus, immersed in this vapour, took fire, and occasioned a detonation still more violent. A mixture of this muriat with the concentrated nitric acid, produced similar phenomena in a yet greater designee.

"These phenomena M. Fourcroy recommends to the attention of philosophical chemists; he ascribes them to the sudden and simultaneous feparation of light, condensed vital air, and oxygenated muriatic acid, from the muriat."—See the Appendix to the Monthly Review, for August 1792, p. 514.†

Now let us attend to the experiment upon the muriat of potash being exposed to the influence of the concentration of vitriolic and nitrous acid, which, having a stronger attraction for the alkali, expels the dephlogisticated marine acid. But in this expulsion it is united to a part of the alkali;

† What makes me anxious in quoting those liberal gentlemen, the reviewers, is, that I found them misconstrue my observations so shamefully: now they certainly cannot contradict their own publications.

and

and the heat generated in the process assists the dephlogisticated marine acid in penetrating and letting loose the fixed fire of which the alkali is formed.* When men have established any hypothesis, they account for phenomena, without adverting whether it is consistent with reason or not.

Let us consider Mr. Fourcroy's explanation.— "He ascribes them to the sudden simultaneous feparation of light, condensed vital air, and oxygenated muriatic acid from the muriat." The muriat is formed from the calx of lead, and, as they fay, from the acid imbibing the pure air of the lead. Now in the condensation of the air, a great quantity of light and fire is produced; feen in the combustion of iron. And, strange! in its expansion it produces the same fire and heat, they say. This is directly against the first principles of their fystem, viz. bodies giving out fire upon their condensation, and imbibing it upon expansion: But these contradictions are of no moment to them. --- Does not the phosphorus produce the same effect, and is it not a combustible body? Are we to lose fight of every former rational fast of our forefathers? As the phosphorus produced the same effect as the alkali with the dephlogisticated marine acid; can we have a doubt but that they both act as inflammable bodies? If our modern che-

^{*} That alkalies are formed of fixed fire, is fully proved by Dr. Bewley; and that they are formed into fire by the combuftion of gun-powder, &c.

mists are so credulous, let them examine the ingredients after the operation, (taking care to avoid from the explosion a waste of the ingredients) and they will find, both a part of the phosphorus and alkali have disappeared. And if the phosphorus is imagined to have imbibed the supposed pure air of the acid, they do not suppose the alkali to have any attraction for it: but they equally produce combustion. Here is a violent combustion, with a great separation of heat and light: and, from these wonderful theories, the acids are faid to be the combustible bodies containing the fire; while the alkali and phosphorus are not taken into the account. How the doctrine of our fathers is mangled! But let me tell chemists, that the fixed alkalies will become volatile; * and that the volatile alkali is combustible.

* Mr. Scheele found that the common oils would become volatile oils, by the fire from lime, becoming foluble in spirits of wine. See p. 175, Experiments on Air and Fire.

Dr. Bewley fays, p. 111,—"The acetite of potash, as "Mr. Lavoisier calls it, is a neutral salt formed of the acetous acid and the fixed alkali. Now, it is well known, that this falt, (as Mr. Lavoisier observes, p. 270) will give out ammouniac in distillation; and by ammoniac he means the volatile alkali. Then, can there be a stronger proof of the truth of our hypothesis, that an acid, when united to other bodies, as salts, earths, &c. concentrates a great quantity of fire, so as to change the fixed to the volatile alkali, as in this process of the acetite of potash? And it also clearly ascertains this fact, that by an addition of fixed sire, the fixed alkali will become vola-

bustible, we well know. Mr. Scheele fays, that if you throw the caustic volatile alkali into a hot crucible, it will burn with violence; and it will likewise form inflammable air, and explode.

The formation of nitre, both to the philosopher and the state, hath long been a desideratum: it will produce the greatest quantity of pure air; and is the

"tile. And it proves, which is a fact of still greater conse"quence, that when an acid and an alkali are exposed to heat,
"they will concentrate a very great quantity of sire: therefore
the nitrous acid, which is an acid of a stronger attraction for
the alkali, and for fixed sire, will, (as we have shewn) in the
distillation of nitre, attract and concentrate a quantity of sire,
and form oxygen gas. All these are fair and clear deductions
from unquestionable sacts.

"With this review, we may be able to account for all the " phenomena of the late numerous experiments made by che-" mifts for these twenty years; and I aver, that there is not one " of these phenomena, but may receive an easy and rational ex-" planation from this hypothesis. When oxygen gas is formed " from acids and earths, we have supposed that the acid, with " fixed fire, and a little of the earth, are aerilized into the neu-"tral aerial falt or nitre, called oxygen gas. That there is a " finall quantity of earth, as much as is necessary to combine "the fixed fire, the acid and water together, is very probable: " for (as Mr. Beaume observes) it has all along been supposed, "by old chemists, to be a kind of basis to salts; and these bo-"dies, I should think, form both oils and falts. That all " bodies, which contain a great quantity of fixed fire, are formed " of acids, water, and earths, is what Dr. Harrington has E 3 66 always

the principal ingredient in gun-powder. I had collected a number of experiments and facts, relating to its formation, some years ago, and meant to have had them published in the Philosophical Transactions: but this avenue to same I sound shut against my discoveries. I have had the audacity to contradict the opinions of some of its first members, and in consequence I must be run down: but as the phenomena elucidate these Essays, I shall give the heads.

Nitre is formed from the putrefaction of animal and vegetable fubflances: but it must be conduct-

" always taught, nay I will venture to fay, proved. But he " proves that the pure air of the atmosphere is not formed of " earth, or the strong mineral acids, but of water and a weak " acid, called the aerial acid, or fixed air; and therefore an air very different from the factitious oxygen gas: but that the of gas may contain a little earth, when made from metals, is very probable. Dr. Harrington fays in his Letter, p. 135. " As our theory supposes that there is a small quantity of earth " in the artificial empyreal air, to ascertain this, I examined, " very accurately, the refiduum, after decompounding the em-" pyreal air by the electric fluid; and I always found a deposi-"tion of an earthly fediment. That the quickfilver could not " produce it, I afcertained, by putting in a column of distilled water between it and the air; fuch a quantity as would dilute "the acid, so as that it could not in the least act upon the " mercury. Besides, if the process is conducted over soap-leas, or lime water, by a chemical examination, you will equally " find that there has been an earthy deposition from the air's "being decompounded." And Dr. Priestley has brought a " number of experiments to prove, that nitrous air contains a f little earth, and how difficult it is to detect it."

ed under the influence of a warm fun, and the ingredients piled together in neither too large a mass nor too small, in order to make the putrefaction as intense as possible; so that putrefaction shall be so highly conducted as to decompound the fixed air into the nitrous acid, the fame as has already been done in intense combustion. And likewise, when putrefaction is so intensely conducted, all the phlogiston, of the putrid mass, will be decompounded into free fire; but this free fire, meeting with a proper basis in the ingredients, will form a faturation of fire, as an alkaline falt. We need not wonder at this, fince, in burning vegetables, &c. a fimilar faturation will be formed. -That lime, from old buildings, will produce nitre, particularly in hot countries. And as those buildings being exposed for a long time to animal effluvia, heat, &c. will have the putrefactive process regularly and flowly conducted by a still conflant fuccession of fresh animal matter and heat: fo that, in a long time, the fixed air is broke down, or changed into the nitrous acid. The nitrous acid, I suppose, generated in those processes, where acids are changed under a great degree of caloric. That all acids may be generated into each other I think is a very clear fact.

When I was upon my experiments in changing fixed air into pure air by the fun and water, I forgot to mention that the fpring water I made use of contained an earth, held in solution by fixed

air, fo that, after a long exposure to the sun, the earth was precipitated. The fixed air uniting to the rays of the sun and water, formed pure air: but it requires a long exposure before this process takes place.†

All

+ And likewife that if vegetable bodies are placed in water, and exposed to the sun; as the putrefaction of the vegetable takes place, it will give out a quantity of fixed air, and this fixed air, by the action of the fun, will be formed into pure air. Now any of these experiments concerning fixed air, which I have mentioned in these Essays, is sufficiently clear to establish my theory. But I will finish my observations and arguments upon it with this fact: the illustrious Bergman, Dr. Priestley, and many others, have found that, in passing the electric spark through common air, fixed air is formed. Now in this experiment the free fire of the electric fire is to that degree of high temperature, that it fets free the atmospheric fire; and the electric fire is to that intensity, that it will dissolve iron in its quick and inflantaneous passage through it. I should be willing to rest my theory upon this experiment alone; for to endeavour to explain it upon any other theory than mine, is ridiculous.

Dr. Priestley says, vol. III. p. 299, "Mr. Metheric found, "p. 146, though nitrous air is obtained from a solution of "mercury in nitrous acid, almost all the acid is found in the solution." And Dr. Fordyce found almost all the acid in the solution of zinc in the vitriolic acid. Then can we have a doubt but both solutions are from the same cause; and not suppose the one from a decomposition of the water, and the other from a decomposition of the acid. The nitrous acid has a strong attraction for metals, the same as it has for calcareous earths; and if I add as much of the acid as to neutralize the earth and metals, and no more; and, if upon examination of them after the satu-

All the trials which Dr. Pearfon put his suppofed charcoal too, prove clearly that it was a species of soot, as the common foot will just produce the same phenomena. But need I hint to the chemical world other more necessary trials; passing the steam of water through it, imbibing air when heated, &c. &c. &c. But indeed I do not know but foot will stand these trials; for the supposition of its being charcoal is so absurd, that I have not spent much time upon it. I have regularly sollowed our philosophers in detecting their errors: but my patience is nearly exhausted. I would advise them to cast about, as the hunter expresses it; for the longer they are in doing it, the more awkroard must their behaviour appear.

ration, I find all the acid, only allowing a little for what the nitrous air took up from the metal; can chemits form the most vague conjecture that the nitrous acid is decompounded in the metallic faturation, as all the acid is found entire, and the same in both the saturations? But still more forcibly to contradict so very absurd an opinion; by passing the electric spark through nitrous air, Dr. Van Morum reduced three-sourths of it into the nitrous acid.—(See a full explanation of this in my Letter, p. 32.) What led to this extraordinary hypothesis, was the experiments of Mr. Lavoisier upon mercury, and which I have shewn can likewise only be accounted for by my hypothesis. See page 56 of these Essays.

Dr. Priestley, Mr. Kirwan, Mr. Cavendish, and others, who used once to make so great a figure in aerial philosophy, are now persectly mute. To what must we impute it?—Time will unravel all things.—But hitherto they have had neither the liberality to contend nor acknowledge.

APPENDIX.

OBSERVATIONS UPON THE REVIEWERS OF LITERARY PRODUCTIONS.

Gentlemen of the Monthly Review,

Your behaviour (from its complexion, the candid reader would call malicious) has been fuch, that in justice to myself I can continue no longer filent. You have been profuse in your criticisms upon my chemical publications; but hitherto I thought them not worthy of notice; nor would I have adverted to them, even now, were it not, that in the statement of my doctrines to the public, you are guilty of the most wilful perversion. From the influence you are under, I knew your criticisms would be fevere, but I always thought they would be liberal and just; that you would not descend to the meanness of misrepresenting my principles, or give a wrong turn to my mode of reasoning. When I first gave to the public my theory upon air, I endeavoured to prove, that the air is not phlogisticated in the act of respiration, but imparts its fixed fire to the blood; and that phlogiston is not an elementary body, but fixed fire; which I proved, by a variety of experiments, and that the air is formed of fixed fire, water, and the aerial acid. You, the monthly reviewers, have negligently, yet arrogantly, discussed this doctrine and treated me with the most supercilious contempt. The whole of your criticisms are made up of pompous declamation; nothing of argument, fave only a curious answer to my arguments and experiments upon putrefaction. And here I would beg leave to quote from Dr. Bewley's Treatife, p. 197, as apropos to my present

present purpose, some powerful arguments I have advanced in proof of my doctrine.-" Dr. Harrington's fystem of airs did " not originate from the experiments of gun-barrels, &c. but " from an accurate observation of nature. Take an egg, and " examine its fluids; they are mild and bland, confifting of " a watery mucus; but expose it to the air, and it will become " highly putrid: its fluids are changed from a pure state to one "highly alkalescent and noxious, emitting a most nauseous "ftench. I need not enlarge upon this topic, as every one " must be acquainted with the phlogistic alkalescent state of its " putrid fluids. Then, how must the egg have received all this " alkalescency? From the air, no doubt, as there was no other 6 body that acted upon it. The air, according to their opinion, " is highly phlogisticated; then the wonder still increases, as "we have not only the phlogiston of the putrid egg, but also "the phlogiston which the air has received, to account for. " According to Dr. Prieftley's explanation, one egg will phlo-" gisticate two thousand gallons of air; therefore, agreeably to " his theory, this egg must have given to the air one thousand " gallons of inflammable air; or, according to Lavoisier, some "ounces of charcoal; or, to others, an immense quantity of " phlogiston.

"My reader must excuse me, if I cannot bring myself to believe, that this fine, mild, bland lymph could posses so much phlogiston, or charcoal, as not only to turn it into a state so highly putrid and offensive, but even to phlogisticate state so highly putrid and offensive, but even to phlogisticate state so fuch a quantity of pure air. And I beg leave to dissent from the opinion of those chemists who believe it; their reasons and chemistry being so very different from mine. To convince their judgment that they are wrong, is perhaps not in my power; yet I hope, I shall be able to convince their stomachs. Let those who hold the opinion I am combating, first swallow a found egg, and then a putrid one, and I am sure their stomachs will be convinced, and of course their heads; the

"fympathy and relation between these two parts of the body, being so near and intimate: after this dose they would, I think, be of my opinion. Mr. Lavoisier is so much struck with the state of putrescency, that he wonders that chemists have not been more attentive to it: some chemists have not passed it by; for, if he will please to attend to what Dr. Harrington says in his publication in 1781, he will there see the process of putresaction fully demonstrated and proved.—
In the putresaction of vinegar, the acid is turned alkalescent. See Dr. Harrington."

Now, Mr. Reviewer, let us difcuss this great argument of yours, as it is the only one in your first criticism that you have brought against me, to prove that you are justified in your damnation of my fystem. It is certainly a most interesting fact, which philosophers have not attended to, viz. the great change that animal bodies undergo, when they putrefy. But here this Reviewer instantly explains it: he fays, brimstone, when it is exposed to heat, is equally as offensive, and slinks. Could any critic, particulary one that fills the honourable chair of the Monthly Review, have made use of such a one. The fulphur, by being exposed to the fire. I readily agree with you, flinks: but is it changed in its qualities from the exposure? is it not perfectly the fame fulphur, or does it injure the air? But I must refer you to Dr. Bewley's expedient of swallowing the eggs. Mr. Reviewer, that you could suppose there is any analogy betwixt the brimftone and egg--What must a poor author fuffer, attacked by fuch an unmerciful critic, with damnation in one hand and brimstone in the other! Dr. W____ ought to have wielded less destructive weapons. A Christian divine ought to have fought with more Christian-like arms. They are only fit for the devil himfelf.

In your next review you fay I hobble after Dr. Priestley.—
If directly to attack Dr. Priestley, in faying, that what he calls
dephlogisticated air is phlogisticated, and what he calls phlogisticated

gifticated air is dephlogifticated,—that the act of respiration is giving phlogiston to the blood, and not receiving it. Now the Dr. Mr. Critic, has given up his first idea, that the great principle of respiration is in receiving phlogiston from the blood. And he has likewise followed me in his opinion that all airs have water for their basis,—and that phlogiston is of an alkaline principle;—and in his last paper upon the firing of inflammable and pure airs, I have shewn in these essays how he has followed me. And these are all the points in which we now agree.

I, in my Letter, addreffed to Dr. Prieftley, &c. fay, that, agreeably to the late doctrines, the composition of water and gun-powder is nearly fimilar. For nitie may be principally formed into dephlogifticated, and charcoal into inflammable air: the two bodies which form water. These are my words, page 2,-" But let us enquire, 1st, That inflammable air (or "phlogiston) and dephlogisticated air form water .- Of all "the fingular changes effected by a chemical process, this is "the most extraordinary. That an alkali and an acid body " would unite and form a neutral body, partaking of neither, " has long been known to chemists; but that charcoal should be " formed into inflammable air, and nitre principally into dephlo-" gifticated air, leaving a refiduum; not quite one half of the nitre. " which Dr. Priestley found to contain no nitrous acid, but an " alkaline basis, (see Dr. Priestley, vol. IV. p. 295) and that " these should form water.

"2d. If we are acquainted with the chemical bodies which compose any compound one, we can make that body. Thus fulphur is formed of the vitriolic acid and phlogiston, and nitre of the nitrous acid and an alkali. The common vitriol (so abundant in nature) of the vitriolic acid and iron: and we can form all these bodies in chemistry.

"Then, agreeably to this rule, we should, by mixing charcoal with nitre, directly make the same body as water; however, by adding the residuum left after making dephlogisticated air,

66 (which,

" (which Dr. Priestley found to have an alkaline basis, and not

" half the weight of the original nitre) to a proper quantity of

" water, they would be exactly the fame; at least formed of the

" fame materials as chargoal and nitre."

The monthly reviewer gives this answer, vol. lxxx. p 339,—

"The author pursues this curious thought a little further; but,

instead of following him, let us try if it will apply to his own

hypothesis. Empyreal air, or vital air, according to him,

consists of phlogiston, water, acid, and earth. Charcoal,

he admits, is phlogiston;* and to throw every possible ad
vantage on his side, we shall take the acid in the very state in

which he affirms it to exist in empyreal air, that is, in the

state of fixed air. If, therefore, we acidulate water with fixed

air, and add to it some powdered charcoal and earth: this

composition, on his own principles, ought to be the very

fame thing with vital air."

But is Dr. Harrington's doctrine to be overthrown by a turnof witticism? By attending to this mighty critic, we may see that he has shamefully and wilfully perverted the truth. The hypothesis, adopted by me above these twenty years, and made public above twelve, is, that pure air is formed of fire, fixed air, and water; and that when the fire is fixed and neutralized with the fixed air and water, it may be called phlogiston, since phlogiston is only fixed fire.

Speaking of charcoal in the fame Letter, I fay again, p. 26, "The theory is fimply this: vegetable bodies are principally "formed of the vegetable acid, with water, and an earthy bafis; which is nature's own compound to attract the fire of the "fun, concentrating it. When it is exposed to the fire, the "fire is concentrated, or attracted into the compound, forming "charcoal; and when the heat is pushed further, there is such

^{*} A direct and intentional error; for in the fame book I expressly make charcoal a factitious body, and the fame through all my publications:

† I suppose no earth in atmospherical air.

" a high concentration, as to form inflammable air; but if an " over proportion of water enters into the compound, a confice derable less quantity of fire enters, and they form fixed air."

In your review, you might as well have faid that your friend fulphur should be added to the fixed air and water instead of charcoal. But in both these bodies the fire is fixed and neutralized with other bodies.—It is thus, Mr. Critic, that you shamefully pervert my theory, and mislead the judgment of your readers. I agree with you, that to produce or not, by proper experiments, pure air from fixed air, water, and fire, would be a fair trial of the truth or falseness of my theory. The rays of the sun are the purest fire, and these, I suppose, nature makes use of. If, therefore, these bodies act upon each other, they will make the purest air, as is evident from well known experiments, which I have mentioned in these Essays.—See p. 40.

The other part of your criticism, in which you endeavour to depreciate the justness of some of my experiments, without trying them, is so much of a piece with the rest of your behaviour to me, that I do not think it merits a reply; I shall therefore leave you to your own resestions.

You have honoured Dr. Bewley with fimilar treatment, and your critical remarks upon his Treatife are of the fame complexion. He brings a charge against some chemists,—a serious one it is, and not easily got over,—that they have adopted part of Dr. H.'s system, without being so honourable as to acknowledge it. Our great reviewer makes use of all his rhetoric in their desence, Dr. Bewley says in a note, that Mr. De Luc adopted Dr. Harrington's idea, in supposing that air injured by respiration, &c. is purished in the clouds, and that sire is a body capable of being chemically attracted. The ingenious author, in the Medical Spectator, p. 153, says, "Chemical philosophers have now pretty generally ceased to consider heat as a quality; they have begun to call it the matter of heat. Dr. Robert Harrington, so long since as the year 1781, has not only con-

"fidered it in this light, but hath suggested that, like other objects of chemistry, it has its affinities and elective attractions."

I compared its attractions to be the fame as that of alkalies and acids, not laying latent, a word Dr. Johnson thus defines; luidden, concealed, secret. But it is chemically attracted and united to the fixed air and water, neutralizing them similar to the neutral salts. Then, Mr. Reviewer, when you speak of the fire which neutralizes the vitriolic and the phlogistic acids into sulphur and phosphorus, will you call their fire latent; or is that which I prove neutral salts to posses, to be called latent heat? Dr. Black, in his very important discovery of heat disappearing in vapour, &c. gives no chemical idea what became of it; but that it laid dormant: and so far was he from supposing it was chemically attracted like other chemical bodies forming phlogiston, that he thought phlogiston was a pure element, as Dr. Stahl did, and not actual fire, chemically neutralized with other bodies.

Our very liberal reviewer does not indeed deny, that Mr. De Luc had adopted the idea after me; but takes no notice of the fecond charge, viz. an opinion that the air is a homogeneous fluid, and Mr. De Luc's adopting it from me; only, he fays, our theories differ, which to be fure they do; and this Dr. Bewley expressly mentions. But what Dr. Bewley afferts is this, that Mr. De Luc had adopted Dr. Harrington's idea of the clouds being nature's elaboratory, as he fignificantly expresses it. And, Mr. Reviewer, even this discovery is certainly a great philosophical object. But I have shewn, not only where air is formed, but also its qualities and composition. This Mr. De Luc does not even pretend to have done.

But, Mr. Reviewer, I may fay, without breach of good manners, that in every statement of my system, you make wrong affertions, on purpose to turn it into ridicule; and your motive in doing so, no doubt, is, that the learned world may take your

word, and difregard it. What a pity it is that fuch illiberal critics should have so much influence in the literary world!—According to you, I affert, "that fire is an element, or simple "substance, most abundant in the upper regions of the atmosuper." I say no such thing; but, on the contrary, that the greatest cold abounds there. But this I say, that bodies in the upper regions must first come in contact with the rays of the sun, and that those rays which are arrested and chemically united to the impure air and water, will become fixed, and so add no actual heat to that part of the atmosphere.

You feem to triumph in the supposition, that fixed air and water, being heavy bodies, will not afcend to the upper regions. I thought none confidered it a disputable point, that the clouds contain a great quantity of water. I readily grant, that fixed air is specifically heavier than atmospherical air; but you must also grant me, that fixed air makes a part of the air that has been breathed; and Dr. Priestley found that airs of different specific gravities did not separate agreeably to their gravities, but still retained their situation with respect to each other.-And it is generally allowed, that expired air is lighter than air that has not been breathed, and afcends in the atmosphere. Upon this idea it was, (as I have observed) that Mr. Montgolfier formed his balloon. If two birds are placed in a cylinder, closed at each end, the bird in the lower end will live longer than that in the upper. But if this does not carry conviction home to you, allow me to mention a fact, which, I should think, ought to have greater weight with you than any conception you can boast of. The gentleman who ascended mount Blanc, found that lime-water became immediately turbid upon the fummit of that mountain.

But I have flewn in my Thoughts on Air, (see p. 297) that air, rendered impure by breathing, becomes again pure, if exposed to the sun; therefore I drew this conclusion, that this change will be produced in any part of the atmosphere. Hence, Mr. Critic.

G

you may make this expired air heavier or lighter, just as you please.

As my theory is gaining ground, you thought you could not be off giving some account of it, and though you have often reviewed it, you had never done it before. But pray, why do you not endeavour to relieve the other gentlemen from the charges laid against them? From your filence we may rationally infer, that you think the task too difficult.

You affect to be witty upon Dr. Bewley's appeal in his dedication to the Royal Society. Whatever you may think, others are of opinion, that, as a body, or as individuals, they should do something; and as to an appeal to the House of Commons, I thought you had not been so fond of it.

You are extremely kind in taking fo much pains to draw up a connected view of the whole theory, though I have but a mean opinion of your ability and candour for such a task. What you have done, is done most admirably. I cannot give you credit for ignorance; no, it must have been with design, that you have fo wilfully perverted Dr. Bewley's meaning. This is upon a par with the rest of your criticisms. You say in the Monthly Review for 1791, p. 438,-" The gentleman would, of perhaps, be more likely to gain his point, by drawing up a " connected view of his whole fystem, detached from the refu-" tations, criminations, and other heterogeneous matters, which " envelope and obscure it. Philosophers could then understand " and examine it with facility; they could judge how far it is, or is not, supported by known facts, or by such new facts as " the author might lay before them; and they could fee where its great strength or its weakness lies. We had attempted " fomething of this kind ourselves, and had bestowed no small " labour on it: but we found it most prudent to desist, lest we " should really mifunderstand some of the author's doctrines, or "be thought to have wilfully mifrepresented them. A short ss example will explain our meaning.

" Fire, when free and uncombined, is, in the Harringtonian " language, actual fire or heat: when united with bodies by " affinity, it is called fixed fire or phlogiston, and it cannot be set " free but by the affiltance of acid. Atmospheric air confilts " of a mild acid; namely, the aerial acid or fixed air; a mild " concentration of fixed fire; and water. In virtue of its acid " and fire, it enters into true combustion on the application of " actual fire: but its own concentration of fire being mild, the " heat produced is not intense, and the combustion is limited; " if it had a high concentration of fire, combustion, once begun, " would fpread till the whole atmosphere was decompounded. " Combustible bodies have a high concentration of fire, and the atmosphere only furnishes acid by which their fire is set free. " Nitre is analogous in composition to air; for it consists of an " acid and an alkali, and the alkali confifts of fixed fire and " water; and therefore nitre supplies the place of air in " combuffion.

" Now, if the only office of air in combustion be to furnish " acid, we cannot understand why any air should be necessary " for the combustion of bodies that abound with acid. We "thought at first, that the acid in these bodies might be united "with their fire in a neutral state, and thereby rendered inac-" tive : but, the author affures us, that, in the air itself, the " acid is neutralized by the fire, and yet that air is combustible " per se, without the contact of any phlogistic substance; so "that (though he happens to be mistaken in the fact) the " neutralization of the acid, according to him, can be no im-"pediment to its agency in combustion. Again, that the " aerial acid, or fixed air, a substance so remarkable for its pro-" perty of extinguishing combustion, should be the primary 66 agent in producing and supporting combustion, appears to us " unaccountable: but this acute philosopher has, doubtless, con-"trived means of counteracting its deleterious power, though " all our attention has not been able to discover in his book any

"intimation of fuch a corrective, nor of any other principle existing in the atmosphere, than fixed air, fire, and water."

A most cunning Jesuitical review this is of my theory. But let Dr. Bewley speak for himself; this is the only way to shew how grofsly the reviewer has perverted his doctrine. Dr. Bewley fays, p. 30,-" Nature has wifely ordained, that the atmospherical "air, a light aerial phlogistic body, should be the agent, by " which combustion is conducted, as being easily susceptible of "taking fire. But then its fire is so light and weak, that it is " not capable of confuming or burning, without the aid of " another combustible body, which is fet on fire by the atmof-" pherical fire being kindled; and then the strong combustible "body, (as a candle for instance) is also lighted, both fires act-"ing together, fo as to keep up the combustion. But were " fire applied to the candle, without the agency of atmospheri-" cal air, no combustion would follow, even suppose the candle " is composed of inflammable materials. For both atmospheri-" cal air and a combustible body are required to produce igni-"tion, and that upon account of the attraction and concentration " of fire. There will be no combustion, unless they both act "at the fame time; or, that intense heat necessary to support "the ignition, or the confuming of the body, will not be pro-"duced. The cause of which is most probably this; the " intense heat produced acts upon the combustible bodies, con-" centrated fire, or phlogiston, so as suddenly to expand them, "and to break their attraction from the bodies to which they " were chemically united. For the confumption of one particle " of its fire, is the means of confuming the neighbouring par-"ticles, and fo on, till the whole body is confumed, or broken "down by the separation of its concentrated fire or phlogiston, " and from the mechanical expansion, a consequence produced " from great heat; fo that the whole texture of the body will " be broken and reduced to ashes. This is evident from intense f' heat, confuming or burning bodies without ignition; viz. " light

"Great heat, will be equally confumed or burnt, as if it had been ignited. But that it is not ignited, is evident from the air not being acted upon by the paper: and the fame phemomenon will take place in foul air, or in vacuo. Hence it is evident that the paper is confumed by having its phlogiston or fire feparated from it by the heat."

Here it appears that the air's fire is first set free, which fire then acts upon the fire in combustible bodies, and sets it free also, and so combustion takes place. But if the air's acid is of service to combustion, it must be by affishing in setting free the fixed fire of the air, with which it is neutralized; and not by its acid acting upon the combustible body. But if you, Mr. Reviewer, like not this doctrine of the fixed air of the atmosphere contributing to the combustion, you may even let it alone, as it alters not my theory: which is this, that pure air, as well as the candle, is a combustible body; that the air is necessary to the combustion, from its fire being so easily set loose; and therefore it acts upon the candle's fixed fire.—But not, Mr. Reviewer, from its acid, viz. fixed air acting upon the fixed fire of the candle, but only upon the fixed fire with which it is connected, in the state of pure air.

And, as Dr. Bewley has shewn, what farther corroborates this theory is; essential oils formed into vapour will not promote the combustion of the candle. But if these essential oils are formed into a vapour or air with the nitrous acid, the dephlogisticated nitrous air of Dr. Priestley, and which I have clearly proved to be formed of the nitrous acid and phlogiston; then this air will allow a candle to burn in it, the same as pure air. Here the acid is necessary to set loose the fixed fire of the essential oils to which it is united. But I will quote one of your paragraphs in the Appendix to the Monthly Review, for 1792, p. 513,—" It was formerly supposed that all those elastic sluids, "which are unsit for respiration, were equally improper for com- bustion: pyrophorus, however, has been found to burn in

" nitrous gas with greater violence than in atmospheric air; and " it appears, from the experiments here related, that the oxyge-" nated muriatic acid gas, or the dephlogisticated marine acid of "Scheele, forms another exception to a notion once fo generally " received. A wax-taper immerfed in this gas continued to "burn; the flame, indeed, became longer and fmaller, and "assumed a reddish hue like that of a torch feen through a " mist: but it was observed that the wax burned faster, and "that the wick was fooner confumed, than in common air: " fimilar phenomena occurred on repeating the experiment with "a lamp; the flame was red and gloomy, furrounded with a " denfe vapour, and the carbonic fubstance of the oil feemed to " be feparated with greater rapidity than usual, and to be " whirled in a kind of torrent around the wick. The phospho-" rized hydrogen, or phosphoric gas of Gengembre, on coming " into contact with the oxygenated muriatic acid gas, immedi-" ately took fire, and burned with a deflagration not less violent "than in the atmosphere, but with a slame less bright than it " yields in vital air. The fulphurated hydrogen, or hepatic " gas, on the contrary, exhibited no inflammability on being " thus mixed."

I do not fay that atmospherical "air is combustible per se." This is slyly afferting, without any qualification, that, agreeably to my doctrine, atmospherical air is combustible per se.—I only say that Dr. Priestley formed dephlogisticated nitrous air, so highly combustible as to explode of itself when fire was put to it. In the year 1785, I proved, in a manner so evident, that this dephlogisticated nitrous air is formed of phlogiston and the nitrous acid, that those who attend to my proofs cannot possibly mistake them. Now, your wonder that fixed air should be the primary agent in combustion, is, no doubt, as great a wonder to me. Therefore, Mr. Reviewer, your learned criticisms are founded upon false data and observation. I would have expected something more acute, at least more just.

But you have not, in this your tremendous review, taken

any notice of Dr. Bewley's general doctrines, nor of his observations upon Dr. Crawford, Lavoisier, Cavendish, Kirwan, &c. By all means keep down the spirit of inquiry, when such refearches are not to your taste. It would have been better not to have entered upon any investigation, but to have pronounced my damnation at once. I have now answered all your mighty objections, or criticisms.

Mr. Reviewer, I shall hint to you that you speak too confidently of Dr. Pearson's experiments on phosphorus, as clearly evincing the formation of charcoal. But a critic who undertakes to decide and direct the public upon these very abstruse and interesting subjects, ought to have some knowledge of the fubiect. Now, Mr. Critic, there are many experiments where this black footy matter has been produced, and where there can be no fuspicion of charcoal forming any part of the process: yea, even where so far from fixed air being decompounded into charcoal in the process, it is even generated. And, Mr. Critic, I will give you your friend Dr. Priestley's experiments to prove what I fay, as you will not certainly dispute what he fays. He fays, vol. VI. p. 116,-" Willing to try the effect of heating "iron, and other substances, in all the different kinds of air, "without any particular expectation, I found that iron melted " more readily in vitriclic acid air than in dephlogisticated air. " the air was diminished as rapidly, and the inside of the vessel " was covered with a black footy matter, which, when exposed to " heat, readily sublimed in the form of a white vapour, and left "the glass quite clean. The iron, after the experiment, was " quite brittle, and must, I presume, be the same thing with "iron that is fulphurated; but I did not particularly examine "it. Of feven ounce measures of vitriolic acid air, in one of " these experiments, not more than three-tenths of an ounce "measure remained; of this two-thirds was fixed air, and the " refiduum of this was inflammable. I had put three of fuch " residuums together, in order to make the experiment with "the greater certainty." Now, Mr. Critic, I need not name

to you, that this air is the vitriolic acid aerialized; and that the vitriolic acid will, along with iron, produce inflammable air.

But when applied under an intense degree of heat, this inflammable air is expelled in the state of this black footy matter. The iron, after the operation, is partly calcined, and quite brittle.

And further, to hammer it more into you, and to oblige you to open your eyes, how unwilling foever; the vitriolic acid air will expel the black footy matter from phosphorus. Dr. Priestley's and Dr. Pearson's experiments are the same; the phosphorus has its fixed fire expelled by an acid; the acid being in one process the vitriolic acid air, and in the other the aerial acid air: and what the fixed air, or aerial acid wanted in strength, is compensated by the great heat Dr. Pearson employed in his process of decompounding the phosphorus.

Dr. Priestley says, vol. II. p. 12,-" A piece of phosphorus " remained a day and two nights in vitriolic acid air, without " fenfibly affecting it. It gave no light in this air; but the "upper furface of it turned black, and the furface of the " quickfilver on which it lay, had a deep yellow or blackish kind " of feum upon it, as if it had been in part diffolved by the acid." Now, Mr. fuperlative Critic, the fleam of water will expel inflammable air equally from phosphorus and iron; and it appears, when expelled under a great degree of heat, and little water, not to give the fixed fire an aerial form. Both in Dr. Prieftley's and Dr. Pearson's experiments, your two friends, it takes the form of a black foot : yes, Mr. Reviewer, even from a letter in your own review, phosphorus, by passing through a glass tube, under a great degree of heat, will deposite this black sooty matter. upon the glass. And this same correspondent formed this black footy matter from phosphorus and lime; the latter not effervelcing in the least with acids, therefore, Mr. Critic, could possess no fixed air, whatever your great authority may fay to the contrary.

That the vegetable acid in wood has a great attraction for fire, is feen in charring: it attracts fuch a quantity, that when it meets with the steam of water, it is aerialized either as the aerial

acid or inflammable air, the proportion of each air depending, as I have before shewn, upon the quantity of water used, and the degree to which the wood is charred. To prove that the aerial acid has a strong attraction to concentrate fire; if it is exposed to the common fire, with water, it will receive a concentration, fo as to form azote; but if exposed to the rays of the fun, receiving a greater proportion, it will form pure air: but if still greater, applied in the powerful state of electrical fire, it will form inflammable air. A well-known experiment .- And to prove what a powerful state of fire the electrical state is. If you pass this electrical fire through the nitrous acid, the acid will receive fuch a proportion of the fire, as to form a nitrous air that will admit of a candle burning in it, with an enlarged flame, just the same as Dr. Priestley's nitrous air formed from the nitrous acid and zinc, improperly called by him dephlogisticated nitrous air: it ought rather to be called phlogisticated; and if the electrical fire is paffed through the phosphoric acid, it will, like the aerial acid, receive fuch a quantity as to form inflammable air.* Now these are well-known experiments. Mr. Critic: which, I suppose, you are a stranger to .-Can we have a more regular connected chain, without running into those wild theories of the decomposition of water and the decomposition of acids: and likewise destroying all our former rudiments, and advancing a thousand other absurdities.

I mean these bints to you and your friends; and that the public may have a fair representation.

Gentlemen of the Critical Review, I refer you to the Medical Spectator Extraordinary: his charges are very heavy upon

• That these inflammable airs are not from a decomposition of water is evident; for in passing the electrical spark through water, in all forms and situations our ingenious chemists can invent, no inflammable air can be obtained. But to shew its formation; if you pass it through the caustic volatile alkali, you will generate it in great abundance.

your criticism of my system. To give a little specimen, I shall quote a few lines: he fays, p. 20,-" Dr. Harrington appeals " to the experiments, which, for a confiderable time, were fup-" poled to demonstrate that WATER may be decompounded, · and that it confifts of inflammable and dephlogisticated airs.— "He afferts, on the contrary, that these airs are themselves de-" compounded; and that WATER, as one of the component " parts, instead of being made, is only deposited or precipi-"tated. Does the critic deny the force of this argument? No "-He admits its truth, but furreptitiously attempts to give "the reputation of it to others; and even lays claim himfelf to "the fame idea in respect to inflammable air-he tells us the " conclusion was fo obvious, that he himself made it long before " he even heard of Dr. Harrington's attempts, and infidioufly " refers his readers to the 65th volume of his Review, which " was published in 1788, eight years after Dr. Harrington first " published his general theory, that WATER is a constituent " part of atmospherical air, and three years after he had in the " most express terms extended the idea to every species of fac-" titious air."

As to you, the gentlemen of the Analytical Review, you make no analysis, you only declaim; and have the boldness publicly and openly to avow this aristocracy in these investigations. What a profanation, for any one to offer to meddle with their researches! Though they should set the Thames, nay even the ocean, on sire, dare any impious tongue cry "hold! hold!" There is the Grand Turk in government, and the pope in religion; but I never heard of aristocrats in science: yes but there are, and who have their janissaries too, (those reviewers) to strangle a poor author at their nod.

In their reviews of my general fystem, they have not made any attack upon my general principles, but only upon some particular and very secondary parts, which they thought they could criticise, or exert their witticisms upon; like to a general who never faces the main body of the enemy, but lies in ambush for a foraging party, or any fmall detachment, and cowardly attacks them, and puts them all to the fword, and then publishes a great and important victory to the world: but sometimes on their return to their camp, from their supposed victory, they, in their turn, get themselves cut to pieces. Such has been the conduct of those liberal gentlemen, the reviewers, and I hope such will be their sate.

I have been informed Dr. Priestley has been very anxious in his enquiries to know who is the author of a Treatife on Air. fubscribed Dr. Bewley. I acknowledge myself to be the author: and how far I am justified in taking a fictitious name, I leave to the candour of the public; my motives being these. I need not name how much my feelings have been hurt by these cruel and undeferved criticisms of the reviewers for these thirteen years: observing that my enemies, without coming boldly to the contest, skulked, allowing the reviewers thus to abuse it; thereby, hoping the public would, without investigation, condemn it. And I found that my name being annexed to any arguments. however forcible, would not be attended to. I aeknowledge I was induced to put a fictitious name to my book. Any man who has experienced those very abusive criticisms in the monthly publications, will eafily admit of my apology, in adopting a scheme which opened a prospect of avoiding such heavy abuse. Nay, I hope the day is not far off, when, instead of condemning me, the world will fee the truth of my doctrines, and the feverity of my ufage, and turn the reproach upon their own heads, as being more deferving of it. Living in a place where these deep aerial investigations are not attended to, my publications are not perused by any one, before they go to the press; and my mind being so intent upon the abstruse parts, could not attend so well to those secondary minutiæ. Those who are not conversant in the subject, but only take their opinion from my good friends, the reviewers, it cannot be supposed I should consult ; therefore I have been left entirely to myself. Indeed I wrote

to one gentlemen, whose judgment I could depend upon, viz. the author of the Medical Spectator, faying that I had a book ready for the press, and asking his opinion of the propriety of a fictitious name, and he agreed with me; but, upon mature confideration, wrote to me not to do it. Having then printed many of the sheets, I did not chuse to reprint them. That I had any defign of deceiving the public, by taking upon me the name of Bewley, I directly deny. The reasons why I hit npon that particular name were, that I wrote the book principally at a country house in the neighbourhood of Carlisle, contiguous to which their lived a farmer, whose name was Bewley; which name I thought an obscure one, and principally confined to the north. That there was a gentleman of that name, who had, in the Appendixes to Dr. Priestley's volumes, wrote a paper or two upon the acidity of fixed air, after Bergman, and one upon the nitrous acid being contained in the atmosphere: but he had been dead for many years. His name was Mr. William Bewly, -I took the name of Dr. Richard Bewley.* Now I suppose that no man could conceive that the dead could publish: besides, after I had my book in the press, his name struck me; therefore, to obviate any millake, I, on purpose, quoted him as another author; and I was certain my good friends, the reviewers, would take care to have the mistake rectified, if there should be any. But these are hard reflections, to think, after my labour and discoveries, I should be under the necessity of taking the name of Bewley, or any other, in order to engage the attention of the public: but the day of retribution will come, and then we shall see whether the reviewers or I are more worthy of condemnation-They are not above the tribunal of the public. I have given a just REVIEW of their conduct to me.

^{*} And to shew that I took the name from the farmer, and not from the chemist, I have spelt the name as it is done by the former, (usual in the north) and not as the latter.
